Dr. ANDREWES and Dr. T. J. HORDER gave a preliminary account of their work on the Classification of the Streptococci Pathogenic for Man. Dr. Andrewes, after mentioning the conflicting views which have been held on this subject, referred to the chemical tests introduced by Dr. M. H. Gordon, which he shortly described. In the hands of Gordon, Houston, and others very marked chemical distinctions had been shown to exist amongst the saprophytic streptococci of the mouth and intestine, in air and in milk. He and Dr. Horder had tested some 200 streptococci and pneumococci from cases of human disease, applying Gordon's tests to each. They had found these tests, on the whole, to give very constant results—i e , a given strain gave always identical reactions, with occasional exceptions. Some reactions were less constant than others, indicating that all the tests were not of equal value. But no one chemical reaction was of absolute specific value. Gordon's tests required to be used in conjunction with other characters and so used they were of the greatest assistance in the identification of the streptococci. The streptococci were a dominant genus which had specially adapted itself to a saprophytic existence in the animal body and were probably rapidly varying in their physiological acquirements Some few forms only had acquired parasitic powers. The species were not yet fixed so clearly as in some other genera. Tabulating the results of some 1300 or 1400 colonies in which Gordon's tests had been applied the result was a bewildering number of chemical types in which no sort of order was apparent till other characters were taken into consideration But amongst the pathogenic forms some five groups of approximately specific value were recognisable. These were as follows: 1. Streptococcus pyogenes, vel erysipelatos, the most typically parasitic and virulent. This was a long-chained form which never clotted milk or reduced neutral red. It gave a positive acid reaction with saccharose and lactose and usually with salicin, more rarely with coniferin and mannite. This was the species responsible for acute suppurations, erysipelatous processes, and many septicæmias. 2. A type which was chemically closely related to the streptococcus brevis of the mouth and intestine but which in disease commonly showed long chains. It was distinguished from streptococcus pyogenes by its power of clotting milk and usually of reducing neutral red, by its lesser virulence, and by the fact that it grew with difficulty on gelatin at 20° C. It was a not uncommon cause of malignant endocarditis and had possible relations with scarlet fever and rheumatism, though no sufficient data were forthcoming for definitely associating it with these. 3 Streptococcus fæcalis: a short-chained form typical of the intestinal canal, not pathogenic for mice, but chemically very active. It habitually gave positive reactions with all of Gordon's tests except raffinose and inulin and sometimes even with these; on the other hand, some reactions might be suppressed. It was common as a cause of cystitis and of terminal septicæmias, perforative peritonitis, and occasionally of meningitis. 4. The ordinary pneumococcus, which habitually gave positive reactions with saccharose, lactose, and raffinose, and often clotted milk; inulin, too, was sometimes fermented. 5. An aberrant pneumococcus, growing well on gelatin at 20° C. and fermenting mannite and saccharose. These types represented the irreducible minimum of groups, of approximately specific value, to which the pathogenic streptococci and pneumococci could be referred. Many intermediate forms occurred and might ultimately prove worthy of recognition as species. The question had a very serious bearing on serum therapeutics, because it was possible in a few days to refer any given streptococcus to one or another of these types and it would be easy to prepare anti-sera against each type. Dr. Horder specified the condition usually called malignant endocarditis as illustrating the importance of these investigations. During the past two years the streptococci isolated from the blood during life and from the heart valves after death in cases of malignant endocarditis had been subjected to full investigation, including the series of metabolic tests already mentioned. The result has been to show clearly that the commonest type of streptococcus present is not streptococcus pyogenes but one or another of the types which occur as common saprophytic organisms in the intestine or mouth. The cases thus examined numbered 16, 13 of which were examined by blood culture upon one or more occasions during life, the organism being isolated by this means. Of the 16 streptococci two only were certainly of the type streptococcus pyogenes. No fewer than eight were of the type, at present unnamed, so common in the saliva. Four were of the type streptococcus fæcalis. In two cases the reactions were not satisfactorily completed. The organisms isolated during life were mostly verified by these same reactions post mortem. One of the two cases in which streptococcus pyogenes was present was a very acute case, fatal in three days from the onset. The other case was much more acute than either of those from which the other two types of streptococcus were isolated. It therefore seemed certain that in the rather common subacute or chronic cases of streptococcal endocarditis the organism was rarely streptococcus pyogenes The significance of this observation was very considerable, as well from clinical and therapeutic as from a pathological point of view. Pathologically it explained the source of the organisms most often picked up from the blood stream by a damaged heart valve. These organisms were the common saprophytes of the intestine or mouth which gained a nidus in the valve and thence maintained a state of septicæmia. Clinically, it explained the very chronic nature of many of the cases in which for a considerable interval the disease might exist without much constitutional disturbance. Therapeutically, it perhaps explained the present disappointing results of serum treatment in malignant endocarditis. For it was unlikely that even the most polyvalent serum was immunised to any extent, if at all, against the saprophytic organisms. It must be remembered that a polyvalent serum was polyvalent in the sense of being immunised against streptococci from different sources, not against streptococci having known differences in their characters.

CLINICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on April 27th, Mr. H. H. CLUTTON, the President, being in the chair.

Dr. G. A. SUTHERLAND exhibited a case of (?) von Recklinghausen's Disease in a male child, aged five years. At the age of six months a swelling of the size of a bean was noticed on the right temple and the right cheek and eye appeared to be growing out of proportion to those of the left side. All these swellings had greatly increased. The child had suffered from rickets and many bony deformities were present as the result. There was a swelling over the right frontal bone and considerable bony enlargement of the left side of the skull. The right eye was enlarged. The right cheek was enlarged and contained nodular thickenings in its substance. Pigmentation in varying shades of brown was present over the frontal swelling, the right upper eyelid, the trunk, the axillæ, and the groins. There was no enlargement of the spleen.—The PRESIDENT remarked that the case resembled leontiasis ossea in some respects but he had not observed that disease in so young a subject.—Mr. W. G. SPENCER had noted that the spleen was not enlarged and that the hypertrophy of the

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

The Use of Rectal Injections of an Antistreptococcic Serum in Gonorrhœal Infections and in Certain Cases of Purpura Hæmorrhagica.

A MEETING of this society was held on April 24th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

A communication by Dr. W. SOLTAU FENWICK and Dr. J. PORTER PARKINSON upon the Use of Rectal Injections of an Antistreptococcic Serum in Gonorrhœal Infections and in Certain Cases of Purpura Hæmorrhagica was read. They stated that during the course of a series of experiments upon the influence of various forms of serum and of mixtures of different sera on diseases commonly met with in hospital practice they had obtained certain results which appeared of considerable interest. This statement applied particularly to that large class of complaints in which the symptoms arose from a gonorrhœal infection, either recent or remote, and it was to such that they would at the present time invite attention. Inasmuch, however, as they had also encountered two examples of hæmorrhagica purpura which rapidly benefited by the same method of treatment it might be excusable to include them in this communication. Cases had been selected from a series of 14 consecutive instances in which the presence of gonorrhœa was definitely ascertained and confirmed by bacteriological examination and in which the symptoms and signs rapidly subsided under the use of the serum after having resisted the various methods of treatment usually recommended for the disease. The details of two cases of gonorrhœal pyæmia were then given, followed by two cases of severe gonorrhœal arthritis. The latter two cases were selected because they were not only exceptionally severe but also represented a second attack of the complaint. In both instances the disease progressed during the patient's residence in the hospital and the pain and swelling of the joints first affected were in no way relieved by three weeks' assiduous attention to the original complaint and the adoption of the ordinary methods of treatment of gonorrhœal rheumatism. In both instances, also, the effects of the injection of the serum were immediate, the pain being relieved after the second dose and the tenderness and swelling rapidly subsiding after the third. The rectal injections being administered by a nurse the patients were quite unaware that anything unusual in the way of treatment was in progress. The fact that in the various cases they had treated in this manner the urethral discharge disappeared along with the other phenomena of the complaint naturally suggested that acute gonorrhœa might also respond to the serum. Unfortunately, however, considerable difficulty was experienced in inducing suitable cases to become in-patients at the hospital or to attend each day at the casualty department so as to permit the effects of the treatment to be watched carefully but the results obtained in the few cases treated suggested that the serum would prove as valuable in the urethral complaint as in its sequelæ. Details of two cases of purpura hæmorrhagica were then given. In the first the condition was associated with chronic pulmonary tuberculosis and was one of the most severe and rapid that Dr. Fenwick and Dr. Parkinson had ever encountered. In the second all the organs of the body were apparently healthy but since the child came under treatment as early as the second day of the complaint it was impossible to say what course the disease would have taken. The fact, however, that after the lapse of 24 hours severe hæmaturia and bleeding from the mouth had set in, seems to indicate that the case would have proved a serious one. In both these cases after rectal injection of serum rapid recovery took place. As soon as they were assured that the antistreptococcic serum exerted an important influence upon gonorrhœal infections a series of control experiments were instituted by means of simple enemata and rectal injections of the anti-diphtheritic and other sera. Normal horse serum in doses of 20 cubic centimetres was likewise employed. In no instance did the patients experience any relief of their symptoms as the result of these experiments, nor did the physical signs of the disease in any way improve until the antistreptococcic serum was substituted for the other forms of injection. The antigonococcic serum specially prepared at the Wellcome Research Laboratories for the treatment of gonorrhœa also proved of no value in their hands. In addition to the ordinary joint lesions of gonorrhœal origin they had met with several cases in which the inflammatory trouble was chiefly situated in the muscles of the lumbar region and spine. In two well-marked instances of this description, where the patients had been confined to bed for three and five weeks respectively and were unable either to raise themselves or to turn over owing to the severity of the pain which such movements induced, three doses of the antistreptococcic serum completely removed the complaint, so that on the fourth day they were able to get up and to walk about without experiencing anything worse than slight stiffness of the muscles of the back. They said that during the last two years they had never encountered a genuine example of gonorrhœal rheumatism, either in hospital or private practice, that was not immediately benefited by an injection of the serum or any case which had suffered from a relapse. It might also have been remarked that the term "an" antistreptococcic serum had been employed instead of a more general appellation. The reason for this was that there were at least seven varieties of antistreptococcic serum on the market but it had only been with one of these—namely, that prepared at the Wellcome Research Laboratories—that the results mentioned were obtained. By this they did not mean to infer that the other forms were useless but that this particular preparation had been the one with which the best results had been obtained. They were informed by Dr. W. Dowson, the director of the Wellcome laboratories at Herne Hill, that this special preparation was termed by them the "polyvalent" antistreptococcic serum in order to distinguish it from several other varieties prepared at the same laboratories and that in its manufacture 43 different strains of streptococcus were employed, taken from such diverse clinical conditions as septicæmia, ulcerative endocarditis, puerperal fever, malignant sore-throat, and acute rheumatism. With regard to the dosage of the serum they found that double the ordinary amount—namely, 20 cubic centimetres—followed by three or four injections of ten cubic centimetres each on consecutive days was usually sufficient in the majority of cases, it being only in gonorrhœal pyæmia and in severe examples of purpura hæmorrhagica that two injections a day were necessary.

Mr. STEPHEN PAGET said that he had been one of the first to receive an injection of antistreptococcic serum for an infection from a case of septic peritonitis and the effect in arresting the spread of infection had been most striking. In the cases described the treatment seemed equally effective in chronic as in acute cases and of equal avail in cases which were or were not of bacterial origin, such as purpura hæmorrhagica. He asked whether Dr. Fenwick and Dr. Parkinson had used it in cases of hæmophilia and suggested it might be of service in those cases.

Mr. CAMPBELL WILLIAMS said that the term "gonorrhœal rheumatism" was most misleading. There were three distinct varieties of the disease: first, a cellulitic form which had all the appearance of an acute suppuration but which on incision yielded only a little clear serum; secondly, an arthritic form; and thirdly, an arthralgic form without any swelling but with considerable pain; this pain he attributed to neuritis and periostitis. The so-called gonorrhœal infection was in reality a mixed infection and due to a staphylococcal and streptococcal infection and it was probably for this reason that the disease yielded to the treatment by antistreptococcic serum.

Mr. J. P. L. MUMMERY said that the fact that the serum acted equally well when injected into the rectum as when injected under the skin was an observation of great importance. He said that the injections were of great value in cases in which septic infections were likely to arise, such as excision of the rectum and in operation on the mouth. He asked about the subsequent history of the patient who was cured of gonorrhœal urethritis, for the greater difficulty arose in curing the gleet rather than the acute stage of the disease.

Dr. PARKINSON, in reply to the PRESIDENT, said that no special preparation was necessary before giving the injection by the rectum. He had not tried the serum in cases of hæmophilia. He regarded purpuric hæmorrhages as due to a bacterial infection or its toxin. The injection of the serum rapidly relieved the pain in the joints and the swelling subsided. He suggested that the serum might be used with good results in gonorrhœal ophthalmia.

based upon the case of an English sailor who was recently under his care at the Royal Southern Hospital. He described the parasite which was the cause of the disease, the mode of infection, the symptoms, the blood changes, and the treatment. He also showed specimens of the adult worms and lantern slides of the worms and of fæces containing ova.

Mr. Rushton Parker related two very different cases of Gall stones. 1. The patient, a woman, aged 45 years, suffered from pain, vomiting, and dyspeptic symptoms suggestive of gastric ulcer. An exploration made in the middle line of the epigastrium revealed adhesions between the pylorus and the liver; when these were freed a stone was felt in the gall-bladder. The stone, which was of the size of a small marble, was removed and the gall-bladder was sewn up at once. The patient went home in a few weeks apparently cured. She returned in three and a half years (1906) saying that the immunity from symptoms had only lasted for two months. On March 8th, 1906, Mr. Parker opened the original scar again and extended the wound downwards to give easy access to the biliary passages. A stone in the gall-bladder was removed, the cystic duct was tied and cut, and the gall-bladder removed. Another stone was found impacted in its neck. The patient made a complete recovery in five weeks. 2. A stout and apparently vigorous woman, aged 71 years, was admitted on Dec. 30th, 1905, with symptoms of intestinal obstruction of three days' duration. Three similar attacks in two years had yielded to copious enemata which brought away large fæcal accumulations. Jaundice was set up in each attack after 24 hours. A small slack umbilical hernia was apparently not involved in the symptoms. The abdomen was opened through the hernia by a transverse incision. General peritonitis, with adhesive yellow lymph and inflammatory thickening of several feet of the small intestine, was found. A hard object felt in the gut one foot above the ileo-cæcal valve was found on removal through an incision to be a gall-stone one and a half inches long and three-quarters of an inch thick. The intestinal incision was sewn up and the abdomen was closed. The patient died three hours later. At the necropsy the liver was found to be enlarged and fatty; the gall-bladder was exceedingly small but was filled with a second calculus less than half the size of the one that had escaped. A perforation in the gall-bladder led to a space under the liver and thence into the duodenum. This suppurating space was shut off from the peritoneum and did not account for the peritonitis. The latter more probably resulted from transudation of septic intestinal contents during the impaction of the larger calculus in various parts of the small intestine The state of the patient's viscera, her age, and the duration of the disease together completed the hazard of the situation.

Mr. R. C Dun read a note on the After-treatment of Cases of Radical Cure of Hernia in Infants and Young Children. The growing tendency to adopt early operative measures was commented on, and a comparison was drawn between the results of operative treatment and those obtained by the use of trusses. The chief points in favour of early operation were the certainty of cure and the short duration of treatment. Many children apparently cured by trusses subsequently developed herniæ in later life, and these recurrent ruptures were liable to be looked upon as acquired. The strongest evidence existed that the majority of cases of inguinal hernia occurring in adult life were of congenital origin. The simplicity and safety of operations for the cure of hernia in infants and young children were explained. Stress was laid upon the importance of obtaining primary union of the wound. The supposed difficulty of preventing contamination by the evacuations in children too young to have obtained control had up to the present stood in the way of a more universal recourse to early operation. The open method of after-treatment devised and published by Stiles of Edinburgh had, after 15 months' trial, given thoroughly satisfactory results in Mr. Dun's hands. This method was described in detail. Its simplicity and the certainty with which it prevented soiling of the wound rendered it the best form of after treatment.

Mr. R. W. Murray read a paper on the Etiology and Treatment of Oblique Inguinal Hernia. He said that although the presence of an inguinal hernia must be due to some weakness of the structures through which the abdominal contents escaped, the question yet to be answered was, What are the chief factors which cause this weakness and so determine the descent of the bowel? He did not agree with the generally accepted division of inguinal hernia into congenital and acquired, and after pointing out the marked difference between a typically congenital and a typically acquired hernia said that the sac of an ordinary inguinal hernia at all periods of life closely resembled the former and bore little or no resemblance to the latter. He maintained that the main factors in the causation of oblique inguinal hernia at all ages were, first, the presence of a congenital or pre-formed sac and, secondly, want of strength in the muscles guarding the internal abdominal ring. Evidence derived from the study of comparative surgery, post-mortem observations, and clinical experience was adduced in favour of this belief. As to treatment, Mr. Murray said that the cure obtained by means of a truss must always be uncertain, for he did not believe that the funicular process ever became completely obliterated by this method. He strongly advocated operation during infancy when a permanent cure could be assured. In operating he usually adopted the same method irrespective of the age of the patient. The essential points of the operation were that the inguinal canal was opened up and the sac excised after applying a ligature to it at the level of the internal abdominal ring. The divided aponeurosis of the external oblique was united by overlapping. In exceptionally large herniæ in adults he had obtained satisfactory results by inserting a rubber pad which rested on the transversalis fascia beneath the internal oblique and Poupart's ligament. A hole in the pad transmitted the spermatic vessels and the cord.—The President thought the statement that all inguinal herniæ were due to the presence of a congenital sac was too sweeping.—Mr. Parker thought that the terms congenital, infantile, and acquired should be abolished. He had advocated the early operation in infants more than 11 years ago. The sac should be obliterated but there was no need to remove it and there was no need to close the inguinal canal in children. He considered that the length of the mesentary was an important factor in the etiology of hernia.—Mr. K. W. Monsarrat said that Mr. Murray had added considerably to the already strong evidence in favour of the view that in the great majority of cases at any rate hernial protrusions took place into pre-formed sacs of congenital origin. He thought that all the evidence pointed to the importance of dealing in the most thorough manner with the sac in all operations and to do this he considered that it was necessary to slit the external oblique from the external ring upwards to a greater or less extent in all cases. Bassini's operation had given excellent results in the hands of many surgeons. He thought that its chief merit was the perfect access it gave to the neck of the sac. There was no doubt that in a considerable proportion of cases there was defective origin of the internal oblique from Poupart's ligament, a defect which had to be remedied by suture. Mr. Monsarrat left the cord undisturbed and sutured the internal oblique to Poupart's ligament in front of it and not behind it, considering that it was a mistake to bring the cord through the muscular layer immediately superficial to the internal ring. The recurrences that took place after Bassini's operation did so at this point—a fact which supported the view that the weak point in the several layers of the wound should not be superimposed.—Mr. G. P. Newbolt considered that though the majority of cases of oblique inguinal hernia had a congenital origin, yet there were undoubtedly cases in which the condition was acquired. The radical operation in infancy was practically always successful but the mortality was a factor to be considered and was higher than that in adults.—Mr. D. Douglas Crawford agreed with Mr. Murray that all oblique inguinal herniæ were probably due to persistence of a funicular process, this view being supported by four cases of hernia occurring in boys about 17 years old, the first appearance being associated with strangulation and at operation each was found to possess a patent processus vaginalis with an extremely narrow neck about one inch in length which had produced the strangulation. He used a simple collodion protection in children, instead of a heavy dressing and spica bandage, which being difficult to keep dry increased the risk of suppuration.—Mr. G. G. Hamilton, Mr. Damer Harrisson, and Mr. T. C. Litler Jones also took part in the discussion on Mr. Dun's note and Mr. Murray's paper.

Epidemiological Society.—A meeting of this society was held on April 20th, Dr. J. F. W. Tatham, the President, being in the chair.—Dr. Reginald A. Farrar read a paper on the Infectivity of Cerebro-spinal Fever, supplemented by lantern demonstrations of its bacteriology by Dr. M. H. Gordon. Referring to papers read tissues was localised to the region of the fifth nerve, just as in morphœa there was a localised atrophy in the same region, and he therefore believed that the case could be explained in the same manner—namely, by a trophic lesion of the fifth nerve.—Mr. GEORGE PERNET and Dr. F. PARKES WEBER, however, considered the case to be one of von Recklinghausen's disease, although it differed from the classical descriptions of that malady. The former suggested that the bony changes in the skull might indicate the supervention of sarcoma.

Dr. WEBER exhibited a case of "Spontaneous" Fracture in the Tarsus in a woman with Argyll-Robertson pupils. The patient was aged 45 years. About 12 months ago the right foot had become swollen and painful and some crepitus could be felt A Roentgen ray photograph showed that a portion of the head of the astragalus was broken off and displaced. There were Argyll-Robertson pupils on both sides, the right pupil being the larger. The knee-jerks were present. No definite history of syphilis was forthcoming but the patient had had five miscarriages. Mercurial inunction had been employed, followed by the internal use of iodide of potassium, with considerable improvement.—The PRESIDENT remarked that the case bore all the evidence of tabetic arthropathy. He had seen such cases in which later other evidences of tabes gradually appeared. He regarded the displacement of the head of the astragalus (shown by the x rays) as being peculiar to what might be called Charcot's disease of the tarsus. Gumma of the tarsus in that situation was practically unknown.—Dr. WEBER replied that the Argyll-Robertson pupil occurred in many syphilitic persons without leading necessarily to tabes, of which disease his patient exhibited no other symptoms. A possible explanation of the bony deformity was that it was a gumma, though the appearances in the radiogram resembled a fracture or displacement of the head of the astragalus.

Mr. PERNET showed a case of Ringworm of the Scalp treated by one sitting of the X Rays. The boy, aged seven years, was first seen in October, 1905, with a patch of ringworm occupying the greater part of the occiput. On Oct. 19th, 1905, he had one exposure of the x rays, according to the Sabouraud-Noiré method (with the platino-cyanide of barium pastille). This was followed by the falling out of the stumps and hairs on the parts exposed. The result was excellent, the hair having grown well. No disease was now present.

Mr. PERNET also showed a case of Lymphangiectodes (lymphangioma circumscriptum) occurring in a woman, aged 26 years. The disease had commenced at the age of five months. There were nine or ten groups of deep-seated vesicles occupying the right side of the chest from the neighbourhood of the axilla. Some hæmorrhage had occurred into the lesions. The majority of the cases hitherto described were of English nationality.—Mr. CAMPBELL WILLIAMS thought that these cases of lymphatic nævus were by no means rare, as many such cases occurred in children attending hospitals and were removed by surgeons.

Mr. W. H. BATTLE exhibited a woman, aged 30 years, after operation for Perforation of a Second Simple Ulcer of the Jejunum into the General Peritoneal Cavity. She was admitted to St. Thomas's Hospital in March, 1903, for perforated gastric ulcer. This ulcer was situated in the anterior aspect of the stomach near the pylorus and was surrounded by a good deal of thickening. It was sutured, the peritoneum was cleansed, and a drainage-tube was left in the lower wound. Anterior gastro-enterostomy was performed on April 9th, 1904, for pyloric stenosis. On May 6th, 1905, she underwent operation for perforation of a simple ulcer of the jejunum which had burst into the general peritoneal cavity. It was a circular clean-cut ulcer, situated about one and a half inches from the line of junction of the bowel with the stomach. The ulcer was sutured, the peritoneum was cleansed, and the two wounds through which this was done were closed without drainage. Finally the patient was again admitted to the hospital on March 14th, 1905, for symptoms of "perforation." At the operation a perforated ulcer was found at the line of junction of the stomach and small intestine. The tissues around it were indurated. She left the hospital on April 12th, having made a very satisfactory recovery. It was of interest to note that there were no adhesions found at this operation; also that there was now no hernial protrusion of any of the scars.—Mr. SPENCER discussed the possibility of anterior gastro-jejunostomy producing a tendency to re-perforation, but it occurred also after posterior gastro-jejunostomy and in his opinion was not dependent on the kind of operation performed.

Mr. BATTLE also exhibited: (1) A case of Post-auricular Fistula in a girl, aged 11 years; (2) a case of Deformity of the Ulna with Dislocation of the Head of the Radius associated with Multiple Osteomata in a girl, aged 15 years; (3) a case of Ulceration of the Alveolar Border of the Upper Jaw on both sides exposing the Antrum in a man, aged 38 years, of 18 months' duration, probably due to tuberculosis or actinomycosis.—Mr. SPENCER referred to a similar case due to glanders.

Dr. A. E. GARROD exhibited a case of Muscular Atrophy in a girl, aged 11 years. The atrophy involved the shoulder-girdle on both sides, affecting only the lower portion of both pectoral muscles, and being most marked in the dorsal interossei of both hands. The muscles did not react to either the faradic or galvanic currents. The atrophy was more marked on the left side and the left leg was weak, the latter dating from a paralytic attack at the age of one year.—Dr. E. FARQUHAR BUZZARD agreed in the diagnosis of hereditary myopathy grafted on to a case of infantile hemiplegia.

Dr. GARROD also exhibited a case of Angio-neurotic Œdema in a girl, aged 20 years. Since the age of 14 years she had had recurrent acute attacks of circumscribed œdema of the right cheek. Polyuria had been noticed to accompany the attacks. In the last attack three months previously the œdema had extended to the nose, both eyelids, and the forehead, and since then the œdema had persisted up to the present time.—Dr. WEBER thought that there was some doubt of the diagnosis on account of the constant recurrence of the œdema in the same place and its final persistence; and Mr. SPENCER suggested that it might be produced by some antral or naso-pharyngeal streptococcal affection.

Dr. LEONARD G. GUTHRIE exhibited a case of Extreme Obesity with Precocious Puberty in a girl, aged three years. The child had always been rather plump but had rapidly been growing fatter during the past six months, since which time the breasts had begun to develop and hair had appeared on the pubes. The child's intelligence was normal.—Dr. SUTHERLAND remarked that in most of such cases of abnormal obesity the intelligence was dull but here it was associated with both normal intelligence and precocious sexual development.—Dr. GUTHRIE, in reply, commented on the interesting association of the obesity and abnormal sexual development and drew attention to a series of 12 similar cases published by Dr. W. Bulloch and Dr. J. H. Sequeira in the Transactions of the Pathological Society. Ten of these were females, who exhibited precocious sexual development, and six of them exhibited obesity; the two male cases showed great muscular development. In six of these cases hypernephroma of the adrenals had been revealed and Dr. Guthrie suggested that the same condition might exist in his case.

Dr. GUTHRIE also exhibited a case of Paralysis of the Left Sixth and Paresis of the Left Seventh Nerves in a girl. aged three years, which had supervened about six weeks ago. There was weakness on the left side of the face and paralysis of the left external rectus. Beneath the left zygoma was a prominent swelling. The head was almost constantly drawn downwards towards the right shoulder. A tuberculous nodule could be seen on the back of the right hand. The gait was slow, shuffling, and unsteady.—Dr. BUZZARD suggested a tuberculous lesion at the base of the brain in the ponto-cerebellar region, spreading to the left cerebellar hemisphere and thus causing the ataxy; but Dr. GUTHRIE inclined to the diagnosis of tuberculous disease of bone in the malar region extending inwards and involving the left facial nerve externally and the left sixth nerve internally. The deviation of the head was probably adopted to avoid diplopia.

LIVERPOOL MEDICAL INSTITUTION.

Ankylostomiasis.—Cases of Gall-stones with Unusual Features.—After-treatment of Radical Cure of Hernia in Infants and Young Children.—The Etiology and Treatment of Oblique Inguinal Hernia.

A MEETING of this society was held on April 26th, Mr. FRANK T. PAUL, the President, being in the chair.

Dr. J. LLOYD ROBERTS read a note on Ankylostomiasis, had no practical sick-room training at all. He affirmed that the ignorance of some holders of the certificate proved this fact. The value of the certificate was therefore indefinite and it conveyed no indication of the knowledge and experience of the holder, who might be well equipped for her work or who might be the reverse. Thus a great injustice was done both to the able and well-trained women holding the certificate and to the public who had no satisfactory guide to the capacity of the nurse they might employ. It was therefore absurd to claim that the restriction of the right to register to the holders of the certificate of the Medico-Psychological Association was any guarantee of efficiency, but rather the reverse. While recognising and giving full credit to the association for its past work with regard to nursing, he urged the unfitness of a self-elected body of medical men to act as the sole arbiters to decide what the training and examination of a mental nurse should be. It was absurd that no one, however able and interested, should have anything to say on the question of the nursing of the insane unless he or she were a member of the association. Its education committee contained no representative of the public, of general nursing, or of the mental nurses themselves. He referred to the report of the Select Committee of the House of Commons on the registration of nurses and pointed out the different treatment allotted to hospital nurses as compared with asylum nurses. He advocated the representation of asylum matrons and nurses on the central body and held that this body should exercise the same supervision over the training of nurses in asylums as it would do in hospitals. He also argued that it would not tend to progress in nursing if the qualification for registration in nursing mental cases were restricted to the certificate of the Medico-Psychological Association He supported the view that the qualification for registration should not be restricted to any one certificate but should be such as might be approved by the central body, thus approximating asylum nursing training to that of hospitals.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on April 20th, Dr. J. Porter Parkinson being in the chair —Mr. W. Milner Burgess showed a case of Psoriasis Guttata in a healthy looking boy, aged six and a half years. The spots commenced when the child was five years of age. They were best marked on the chest, the abdomen, and the anterior and inner surface of the thighs and back —Dr. Edmund Cautley exhibited a case of Atelectasis of the Upper Lobes of both Lungs occurring in a female infant born at full time and now aged 31 days. There was no history either of cyanosis at birth or of attacks of lividity. There had been cough for two weeks.—Dr. R M Beatty (Belfast) read notes of a case of Chloroma in a young child for Dr. J. McCaw (Belfast). The patient, who was aged 18 months, was admitted to Belfast Hospital for Sick Children on Oct. 30th, 1905, with a history of having been ill for three weeks. On admission the child seemed to be well developed and well nourished. He was markedly anæmic and had a peculiar frog-like appearance, due to proptosis, to swelling and ecchymosis of the eyelids, and also to swellings of about the size of a Tangerine orange in each temporal fossa. The proptosis and swelling were greater on the right side than on the left. The swellings were hard, dark coloured, and gave no evidence of having fluid contents. A tumour of the size of an egg was situated over the upper part of the sternum, similar to those in the temporal fossa. The glands in the groin were swollen, hard, and black coloured, but not tender. The axillary glands were slightly enlarged. The lower end of the left femur was swollen and very tender on movement. The gums were not healthy but were neither swollen nor spongy. The heart and lungs were healthy; there was no enlarg ment of the liver or spleen. The urine was normal and the bowels were open. The child's temperature was 99 4° F. He became gradually worse and died three days later. No post-mortem examination could be obtained. An examination of the blood showed marked variation in the size of the red cells, which varied in diameter from 5μ to 11μ. Two-fifths were over the average size and some were undoubtedly megalocytes. Many of the normoblasts were in mitotic division —Mr. Robert Campbell (Belfast) read a paper on Inguinal Hernia in Children, giving an analysis of 305 operations for radical cure He said that it was generally admitted that treatment by trusses was uncertain in its results and prolonged and irksome to the patient, whereas by operation a permanent and complete cure could be obtained within a fortnight. He quoted statistics to show that 34 per cent. of his cases were operated on under six months of age and 44 per cent. under one year. He thought that the danger of sepsis in infants had been greatly exaggerated. Only two out of the 305 cases had been attended with suppuration. In referring to the contents of the sac he said that the frequency with which the cæcum and vermiform appendix descended in children was remarkable. He mentioned two cases in which the appendix was found adherent at its tip to the bottom of the sac; and another case in which a large Meckel's diverticulum was in the same condition. Strangulation was not frequent or acute in children. He had operated on 16 cases; most of them were under one year of age, two being 21 and 24 days old. As regards after-treatment his usual plan was to remove the stitches on the fifth day and paint the wound with collodion. The mortality should certainly not exceed 0·3 per cent. The radical cure of hernia in children might, therefore, as regards risk be classified with many so-called minor operations.

CORK MEDICAL AND SURGICAL SOCIETY.—A general meeting of this society was held on April 11th, Dr. R. P. Crosbie, the President, being in the chair.—Dr. J. Cotter read notes of a case of Ectopic Gestation. The patient was a woman, aged 36 years, and had been married nine months. Menstruation was regular up to Nov. 20th, when she missed a period then due. A week after this the period came on, heavier than usual, and lasted four or five days. On Dec. 4th she experienced severe pain in the lower part of the abdomen and felt as if something had given way inside. She became very faint and vomited. A week after a swelling in the lower abdomen appeared which gradually increased. When first seen by Dr. Cotter she was profoundly anæmic, with raised temperature and pain in the lower abdomen, where there was a fluctuating tumour. Per vaginam fluctuation could be felt over a swelling in Douglas's pouch and the uterus was pushed forward. He operated on Dec. 24th, first tapping the tumour through the posterior fornix, and got nothing but pure blood. The abdomen was then opened by mesial incision and what looked like a large ovarian cyst immediately presented. On opening it a large collection of blood, fluid and clotted escaped, the clots being ladled out with the hand. At one side of the cyst wall, somewhat in the situation of the outer end of the left Fallopian tube, was what appeared to be a lump of organised lymph. A portion of this was removed and Dr. A. E. Moore reported that it showed chorionic villi and decidual tissue. The cavity was packed with iodoform gauze and recovery was uninterrupted. Dr. Cotter remarked on the great rarity of such cases and thought that this was a tubal abortion, as there was no evidence of a rupture of the tube.—Dr. Cotter also read notes of a case with obscure abdominal symptoms. A man, aged 20 years, after a few days of malaise, had acute pain in the abdomen with vomiting and great collapse. There were tenderness and some rigidity over the right iliac fossa. Thinking the appendix implicated he opened the abdomen and beyond some serous effusion found nothing abnormal. The patient sank and died the next day. On post-mortem examination the pancreas was found greatly enlarged and somewhat bile-stained, with a peculiar "marbled" marking of its surface. There was no evidence of inflammation or degeneration and the cause of death remained unknown.—Dr. H. R. Townsend read notes of a case of Acute Appendicitis in a girl, aged ten years. He saw her the day after the onset of symptoms. There were severe paroxysms of pain referred at first to the umbilicus and later to McBurney's point. He found a deeply congested appendix which he removed. Dr. Moore examined the viscus and found unmistakable evidence of early pus formation. Dr. Townsend said the case illustrated the necessity for instant operation in acute cases.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Manchester on April 27th, Mr. R Favell, the President, being in the chair.—Dr. J. E Gemmell (Liverpool) showed a Fibromatous Tumour of the Labium Majus whose central portion was of the size of a large orange and which had extensions of considerable size into the buttock and also toward the inguinal ring. Dr. Gemmell also described two cases The first patient was 44 years of age, had been married 25 years, and had had ten pregnancies. She complained of pain, abdominal swelling, and interference with by Dr. Bruce Low and others on the disease and to the classic work of Hirsch on its epidemic history he would, he said, confine himself to the one question of its infectivity. He admitted that the medical officer of the Local Government Board in 1888, Professor Osler, Dr. Latimer in America, and the late Dr. J. S. Bristowe, Dr. Hilton Fagge, and Sir Burdon Sanderson held that it was not directly communicable or only so in a slight degree, Sir Burdon Sanderson's conclusions being based on his observation of a great epidemic on the lower Vistula in 1865. Yet, since there was no suggestion of its being water-borne or conveyed by insects, the behaviour of the disease in epidemics could not be explained save by direct personal infection or conveyance by fomites. If so, the consideration of the best means for its repression was an urgent duty, for so far as official returns could be relied on it was greatly on the increase in this country and in America, while it had long been prevalent in Russian and Prussian Poland, and outbreaks were constantly being reported everywhere from Norway to New South Wales and from Ceylon to Nigeria. Dr. Farrar then proceeded to adduce evidence of the infectivity of cerebro-spinal fever in the occurrence of multiple cases in single houses, the implication of "contacts," especially of attendants on the sick, and its conveyance by persons, either themselves or by means of their clothing, to others, often in distant and widely scattered villages, as reported by Dr. Gifford of Boston, U.S., in 1873; Bolton Corney in Fiji in 1888, Friis of Copenhagen in 1891, and still more recently by E. Sweet about Crowborough, Hope Reford in co. Down, Ch. Boldman and Mary Goodwin of Boston, U.S., Walker around Spilsby and Arthur in the Easington rural district; the last two he treated in detail. Hirsch, in a paper read before the society, came to an opposite conclusion from Sir Burdon Sanderson in regard to the epidemic of 1865. Though cases were on record of outbreaks in which either the garrison or the civil population of the town was alone attacked, there appeared to be a special tendency to the occurrence of epidemics in barracks and to the spread of the disease by the movement of troops from infected to healthy places and *vice versâ*. Bouet in 1841 to 1849 collected a large number of such instances occurring at Orleans, Strasburg, Marseilles, Avignon, Nimes, and other places, Petersen at Berlin in 1896, and Jaeger at Ulm in 1893–99. Although intracellular micrococci were not easily kept alive *in vitro* there was reason to believe that in a mucous or albuminoid covering they might, even when dried, retain their vitality for long periods. Jaeger obtained cultures from the dust of the floors of the barracks at Ulm after 96 and 127 days and gave instances of infection otherwise inexplicable, and Germano and Max Neisser classed Weichselbaum's diplococcus among organisms most resistant to drying. When the severest cases alone were taken into account the fatality was over 50 per cent., but a very large number of milder cases erroneously diagnosed or even unnoticed would, if duly included, reduce the percentage considerably. The extreme virulence of the infective material in some cases might be due to the symbiosis of other cocci, as the micrococcus catarrhalis or Fraenkel's diplococcus of pneumonia. The rapidity with which this virulence was lost by successive cases in the course of an epidemic and during convalescence was remarkable.—Dr. Mervyn H. Gordon said that the micrococcus of Weichselbaum, which was undoubtedly the specific organism of cerebro-spinal fever, had a distinct individuality and should always be looked for in suspicious cases. The spinal fluid yielded pure cultures and lumbar puncture was practically free from danger; it was generally present in the nasal mucus, mostly mixed with micrococcus catarrhalis, and might be found in the blood. Elser of New York found it in 7 per cent. Its characters were well marked; it was essentially intracellular, negative to Gram's stain; its colonies in broth were large and smooth and translucent, would not grow on gelatin at 22° C., but flourished on nutrose acetic agar. It decomposed glucose, galactose, and maltose with an acid reaction, but not saccharose. Besides other points of difference many of the nasal micrococci were Gram positive, but micrococcus catarrhalis with a few others were negative and might be confused, though micrococcus catarrhalis was, as a rule, larger, its colonies were more opaque, grew well on gelatin at 22° C., and with sugars gave a strongly alkaline reaction. It, too, might be intracellular and distinctly tetrad, so that the reaction with saccharine media alone sufficed for determination. Both were liable, especially on broth, to become streptococcal or staphylococcal, as, indeed, were all micrococci, and the colonies in agar were surrounded by a halo which was broader than in the meningococcus. The pneumococcus was positive to Gram, its colonies resembled but were smaller than those of the meningococcus, and in albuminous fluids it appeared as diplococci in capsules. The cocci were often so elongated as to resemble bacilli. Experiments with disinfectants variously diluted on equal quantities of cultures of the meningococcus and the effects noted at the end of 30 seconds' and three minutes' contact respectively showed that medical izal was twice as efficient as mercuric chloride or potassium permanganate in practical solutions. Gargling for five minutes with 100 cubic centimetres of izal, liquor chlori, or permanganate of potassium in various dilutions was followed by a reduction in the number of bacteria in the pharyngeal mucus to the extent of 80 or 90 at the end of the first hour, but after another hour the numbers were nearly, or quite, as great as at first. According to the results so far obtained medical izal was best *in vitro* and permanganate of potassium best *in vivo*, 1 in 200 of permanganate of potassium being rather irritating but most efficient, 1 in 1000 not irritating and fairly efficient, whereas 1 in 10,000 of permanganate of potassium showed some reducing effect one hour later but not (as 1 in 1000) still perceptible two hours later.—Dr. T. J. Horder considered that a careful study of the sporadic cases might throw much light on the origin of epidemics. Books described them as mild, but they were often *foudroyant*, as that of a medical man who recently was attacked at a hotel and died within 48 hours. His spinal fluid swarmed with the cocci, but there had not been time for the development of meningeal phenomena.—Dr. F. E. Fremantle regretted that no official inquiry was being conducted in Nigeria where, as he had heard from his brother, the natives were dying by thousands and several medical men had succumbed.—Dr. Tatham cautioned the members against attaching much value to the official returns of the mortality; the diagnoses were most untrustworthy.—Dr. Farrar, in reply, said that not only sporadic cases but epidemics might be caused by other organisms than the meningococcus of Weichselbaum.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.—A meeting of the Northern and Midland division of this society was held at the Borough Asylum, Rowditch, Derby, on April 19th, at the invitation of Dr. S. Rutherford Macphail, who presided.—After routine business there was some discussion on the proposal to unite with the London medical societies in forming a Royal Academy of Medicine. The following motion was carried:—

> Seeing that the Medico-Psychological Association is a national organisation with membership in England, Wales, Scotland, and Ireland, and that the proposed Academy of Medicine appears to be a purely London institution, the Northern and Midland division does not see how any affiliation is possible.

—Dr. Nathan Raw (Liverpool) read a paper on the Mental Disorders of Pregnancy.—Dr. John Richards (Leicester) read a paper on the Histology of Some Cerebral Tumours, in which he first gave a brief account of the clinical histories of three cases of cerebral tumour and then considered their histological features in detail. The first two were cases of rapidly growing tumours of under 12 months' duration and scarcely to be distinguished microscopically from small round and spindle-celled sarcomata. The tumour in the third case was probably of several years' growth, and was composed of well-formed glial cells and fibres closely resembling the normal elements of the neuroglia. Dr. Richards dissented from the view that gliomata were derived entirely from epithelial tissue and held that neuroglia elements also took a part in their formation.—Dr. W. Harding (Northampton) then opened a discussion on the Training and Registration of the Asylum Nurse. After stating what he considered ought to be the minimum training of an asylum nurse he mentioned that a three years' course of training had been in existence at Berry Wood for 16 years but that only about 16 per cent. of the nurses who entered the service gained the certificate. He spoke in strong terms of the inadequacy of the system of training and examination of nurses carried on by the Medico-Psychological Association. He pointed out that the only thing in which there was uniformity was the written examination, the least important method of gauging a nurse's efficiency. There was, however, no uniformity in the more essential parts of the examination while the candidate might actually have of such laboratories to produce over and above the ordinary routine examination of morbid products necessary for the immediate treatment of the patient.

The subject matter of the book is arranged on a clinical basis, the varieties of peritonitis caused by different clinical accidents, such as disease of pelvic organs, perforation of hollow viscera, appendicitis, and so on, being treated in successive chapters. A description of the technique employed shows that an examination of the peritoneal exudation was made by culture and by smear preparations not only at the seat of the primary lesion but, on every possible occasion, at points distant from the original focus, and the results obtained show the importance of this method and how extremely misleading the examinations would have been had they been confined to the neighbourhood of the original lesion.

Among the more important bacteriological results of the inquiry are the discovery of the frequent presence and apparent clinical importance of a staphylococcus albus believed to be identical with Welch's staphylococcus epidermidis albus, the rehabilitation of the bacillus coli as one of the most important organisms in the causation of peritonitis, and the failure to find any support for the teaching that anaerobic organisms play the most important part in some varieties of peritoneal infection. In gastric ulcer a streptobacillus was isolated in every case from the edge of the ulcer, but it is not pretended that this organism has been proved to be the cause of the disease. The staphylococcus albus is an organism of low virulence, found at points of the peritoneum distant from the primary lesion and leading to an active local leucocytosis and phagocytosis. Its presence is regarded by the authors as justifying a favourable prognosis, as modifying largely the virulence of the bacillus coli often associated with it, and as contra-indicating too active flushings and washings of the peritoneum in the treatment of those cases in which it occurs and in which it sets up a protective phagocytosis. The influence of this organism is the subject of a special experimental research incorporated in this book. The bacillus coli, as has already been mentioned, is regarded as of great importance in the causation of peritonitis and especially in that form of it which is associated with appendicitis. The virulence of the organism in different cases and of the different strains isolated from the same case varies greatly. A startling result obtained by the authors was that 55 out of 74 strains of bacillus coli isolated were non-motile and motility was not acquired by cultivation on various media nor by passage through animals. The occurrence of this organism alone and not localised is of bad augury for the patient, but the prognosis is improved if the bacillus coli is localised and especially if it is associated with the staphylococcus albus. Other organisms found were the streptococcus pyogenes and the diplococcus pneumoniæ leading to an invariably fatal result, and the bacillus pyocyaneus also of serious import. A short chapter deals with the rôle of the phagocytes in peritonitis and the conclusion is reached as the result of experiment that not only is the small lymphocyte phagocytic but that the eosinophile cell possesses phagocytic properties of the greatest importance.

The book is a valuable contribution to the scientific study of peritonitis and forms a solid basis for conclusions of value for prognosis and treatment.

Précis de Diagnostic, Clinique, Microscopique et Parasitologique. Par les Docteurs JULES GUIART et L. GRIMBERT. Paris: F. R. de Rudeval. 1906. Pp. 960. Price 15 francs.

THE authors of this manual state that no similar work exists in French medical literature. They have undertaken to produce a book dealing with modern methods of clinical investigation which owe their origin to chemistry and other branches of natural science. In the preface, which naturally, perhaps, tends to the glorification of their subject, they refer somewhat slightingly to those members of the medical profession who are content to ignore the advances of the methods of the laboratory. In fact, they compare the point of view to that of a surgeon who in these days might scorn the methods of antisepsis and asepsis. While we may urge that perhaps they attach too little importance to clinical methods of investigation of disease, there can be no doubt that they have succeeded in producing an admirable handbook. They deal in turn with general methods of investigation, such as bacteriology, in connexion with which they describe in detail the various methods of fixation, colouration, and measurement. In the second part of their volume, in separate chapters, they deal with the following subjects: the blood, pus, pathological liquids, milk, nasal secretions, and expectoration; the examination of material derived from the mouth, the pharynx, the stomach, the intestine, and the liver; with diseases of the skin, the ear, the eye, and the genital organs, and with the urine; while a concluding chapter is devoted to the various reagents employed in chemical analyses. The volume is profusely illustrated, both with plates of instruments employed in the various methods of research and with numerous coloured plates which fairly depict microscopical appearances; these latter are perhaps too diagrammatic—in fact, the illustrations generally sacrifice colour to clearness.

In the section relating to the examination of the blood the information is full and the directions are lucid, while throughout the volume the ease of diction facilitates the work of the student. The principle adopted is to describe normal conditions at some length before proceeding to the consideration of the modifications due to disease. Thus in the section on the blood the methods of enumerating the red corpuscles are given at length before the variations in size and shape are described. Necessarily much space is devoted to the modifications which leucocytes undergo. Then non-parasitic diseases of the blood are dealt with and the bacteriology is considered, typhoid fever, cholera, plague, dysentery, Malta fever, pneumonia, and tuberculosis being described under the heading of Serum Diagnosis. Much space is given to the description of the changes in the blood in malarial conditions, the diagrams in this connexion being extremely serviceable. Small figures are given of trypanosoma Gambiense, spirochæta Obermeieri, as well as of other parasitic conditions affecting the blood. The section relating to pus appears somewhat brief after the fulness of detail of the preceding section. Greater space is, however, given to a description of the methods of examining various pathological liquids. Thus the modifications of fluid removed from the pleural cavity are described in detail with the assistance of numerous illustrations. Reference may also be made here to the description of the examination of the fluid removed from hydatid cysts. The illustrations of the scolex and of the booklets should be especially welcome to students. It is interesting to find that much space is devoted to the macroscopic examination of expectoration from which valuable information may be derived without the necessity of laboratory investigation. Full details are, however, given of the microscopic appearances connected with different diseases, the bacteriology also being elaborately supplied with diagrams.

We do not attempt to indicate categorically the fulness of detail in this text book. We would, however, call attention to the excellence of the illustrations of the parasites connected with the various affections of the skin, while we must confess to some surprise at the tests for albumin in the urine, which do not strictly accord with those commonly employed in this country. The latter are mentioned in small print as being of minor importance. In conclusion it may be remarked that, although due cognisance is taken of the bladder and rectum. Two masses reaching the umbilicus were felt in the abdomen, the larger being continuous with a mass filling the *pelvis. On opening* the abdomen the larger mass was found to be a cervical fibroid, the smaller one being the uterine body. The fibroid was enucleated. An opening was made into the vagina and the bed of the tumour was drained into the vagina by gauze packing, the peritoneal cavity being completely closed. The central portion of the tumour was undergoing a form of degeneration closely resembling sarcoma. The second patient was 47 years of age and the mother of seven children. She complained of an abdominal swelling of six months' duration. Menstruation was regular. The tumour was a fibroma of the ovary weighing 4 pounds. The abdomen contained some ascitic fluid.—Dr. D. Lloyd Roberts (Manchester) mentioned the case of a patient, aged 28 years, who was admitted to hospital at the fifth month of pregnancy with a Retroverted Uterus. There had been dribbling of urine for five days and on a catheter being passed 80 ounces were withdrawn. The bladder was kept empty but necrosis of a portion of its wall occurred and the patient died five days later.—Dr. W. Blair Bell (Liverpool) showed some Light and Useful Retractors for Pelvic Surgery, the blades being constructed of stiff wire and having large fenestræ.—Dr. H. Briggs and Dr. J. H. Willett described two cases of Multiple Fibromata in which there was polypus formation due to the extrusion of fibroids into the uterine cavity, accompanied by adeno-carcinoma of the endometrium.—Dr. A. Stookes (Liverpool) mentioned a successful case of Cæsarean Section for Pelvic Contraction in which the pulse suddenly ran up to 160 per minute at the end of the operation. The same evening the patient's temperature was 103° F. and the pulse 140 per minute. No cause for this could be ascertained and the patient's condition became normal within six days.—Dr. W. Walter (Manchester) showed a specimen of Pyosalpinx with Adherent Appendix Vermiformis.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 24th, Dr. A. Mantle being in the chair.—Dr. A. Bronner showed: (1) A case of Cerebellar Abscess; and (2) a case of Plastic Operation for loss of the Left Nasal Ala.—Dr. T. W. Hime showed an Improved Wash Bottle.—Dr. F. W. Eurich showed a patient with Erb's Paralysis.—Dr. Bronner read a paper on Epistaxis, in the course of which he drew special attention to the following points: (1) in all cases of *epistaxis* the nares should be carefully examined; (2) the bleeding point would in most cases be *found to be on the anterior part of the* nasal septum; (3) that epistaxis was often due to constitutional disease and to nasal obstruction; (4) it was very dangerous to leave a plug in the nares for more than 24 hours; (5) before and after any intra-nasal operation the nares should be, so far as possible, thoroughly *disinfected and all instruments* carefully sterilised and the nostrils then plugged with antiseptic gauze for 24 hours to prevent hæmorrhage, especially if adrenalin had been used; and (6) the extreme usefulness of the application *of hot water, ferripyrin, and peroxide* of hydrogen for arresting hæmorrhage.—The paper was discussed by Dr. T. J. Wood, Dr. W. Mitchell, Dr. Hime, Mr. R. Mercer, and Dr. Mantle.—Dr. Bronner *then replied.*—Dr. Mitchell read notes of a case believed to be Internal Anthrax treated with Sclavo's serum. The patient recovered. He pointed out how impossible it was to *discover the* bacillus in the blood until just before death and how important it was, *therefore*, in any case of suspected internal anthrax, to begin serum treatment early and to use large quantities. He insisted that they had as much right *to diagnose* internal anthrax from symptoms only as they had *to diagnose* many other well-known diseases where the bacillus was not in evidence—e.g., scarlet fever and measles. It was manifestly unfair, he said, *to* say a case was *not* internal anthrax because it recovered.—The *paper* caused a very interesting discussion, in which Dr. J. H. Bell, Dr. Eurich, Dr. Hime, and Dr. H. J. *Campbell took* part.—Dr. Mitchell then replied.

LARYNGOLOGICAL SOCIETY OF LONDON.—A meeting *of this* society was held on April 6th, Mr. Charters J. Symonds, the President, being in the chair.—Dr. H. J. Davis showed a case of Sudden Loss of Voice of 14 days' duration, for diagnosis. The left cord was fixed. *Opinions* expressed were in favour of it either being due to tubercle or syphilis.—Dr. Davis also showed a man suffering from Nasal Obstruction following Facial Paralysis. The condition had improved under *electrical* treatment.—Dr. E. B. Waggett exhibited a case of Absence of the Right Choana.—Dr. StClair Thomson exhibited a patient, aged 16 years, with Laryngeal Stenosis. The case was shown for diagnosis, which rested between functional spasm or bilateral paralysis. He was inclined to view the case as one of functional spasm.—Dr. A. Logan Turner exhibited specimens and drawings showing various pathological conditions of the Nose and Throat.—Mr. P. R. W. de Santi showed a patient with a large Cauliflower Growth of Malignant Nature in the Nasopharynx *and an enlarged deep-seated* Gland in the Neck. The case was regarded as inoperable. It was recommended to put the patient on iodide of potassium.—The President showed a patient with Carcinoma of the Naso-pharynx, which he *regarded as inoperable.—Cases were also shown* by Mr. H. W. Carson, Dr. E. Furniss Potter, Dr. J. Donelan, and Dr. J. Dundas Grant.

THERAPEUTICAL SOCIETY.—A meeting *of this society was held* on April 24th, Sir T. Lauder Brunton being in the chair.—Dr. James Burnet read a paper on the Therapeutic Action of the Iodides, showing that they were alteratives which influenced metabolism and secretion. He said they had long been used against syphilis *and scrofula* and more recently *for* gout, *rheumatism*, aneurysm, and arterio sclerosis. They were formerly supposed to act by dilating arterioles and diminishing the blood pressure but they had no effect on the blood pressure or pulse, though they *promoted* the coagulation of the blood. He found iodopin, iodine with *sesame* oil most effectual injected under the skin, as this did not cause any gastric disturbance and the iodine was slowly set free by oxidation. It relieved arterio-sclerosis by diminishing the uric acid dissolved in the blood and thus relaxed arterioles and relieved aneurysm, if syphilitic, by removing pathological effusion and counteracting the poison. In angina pectoris it must be given in large doses, 60 grains daily for months. It was most useful in chronic pulmonary *diseases*, especially fibrosis and emphysema, relieving dyspnœa and liquefying the bronchial secretion, and it was best given in *doses* of 15 *grains at bedtime. In bronchial* asthma doses of ten grains every two hours were very useful either by relieving spasm or freeing the blood from uric acid. *In* syphilis it was most useful from its antitoxic *powers and* its eliminative action, particularly in affections of the nervous system and headache. In locomotor ataxy 120 grains had *been given* daily with the best *results*. It had also been used with success *in cases of intermittent* fever, puerperal fever, and erysipelas. In chronic rheumatism, neuralgia, lumbago, and sciatica *iodide of potassium* was often *useful, probably* by *diminishing* the uric acid dissolved in the blood; it was best combined with salicylic acid, which eliminated this acid. In cases *of effusion, especially* from interstitial nephritis or cirrhosis, iodides often were of service. In *lead or mercurial* poisoning they *removed the metal* from the tissues and caused its excretion. In simple goitre they were of great service if used early but not in exophthalmic goitre. The iodide of sodium was *less depressing* than that of potassium.

Reviews and Notices of Books.

The Bacteriology of Peritonitis. By LEONARD S. DUDGEON, M.R.C.P. Lond., Bacteriologist to St. Thomas's Hospital, Director of the *Louis* Jenner Clinical Laboratory and of the *Pathological* Laboratories, St. Thomas's Hospital, &c.; and PERCY W. G. SARGENT, M.A., M.B., B.C. Cantab., F.R.C.S. Eng., Surgeon *to* Out-patients, Victoria Hospital for Children, Chelsea; late Resident *Surgeon* and Surgical Registrar, St. Thomas's Hospital, &c. London: Archibald *Constable* and Co. 1905. Pp. 243. *Price 7s. 6d. net.*

THIS work formed the *basis of* the Erasmus Wilson lectures for 1905, the main teachings of which were summarised in a leading article at the *time.*[1] *The book* is welcome as being amongst the first fruits of the establishment of clinical laboratories in *connexion* with hospitals, being an example of work *constituting an advance* in medicine and surgery which it is the proper function convection are those picked out by the supporters of that theory as especially favouring it." But Dr. Stevens must not be classed here with the antivaccinationists who, he complains, "abuse the plaintiff's attorney," for it is only people with a bad case who resort to this, and, of course, Dr. Stevens's case is good. Further, he holds that "if aerial convection be an established fact it should show its influence round each and every small-pox hospital," but as for himself he urges that "any cases, however, in which the special incidence is to the north-east of any hospital should be rather discounted on account of the prevailing wind being from the south-west." We quote this without venturing to expound its meaning.

---

[1] THE LANCET, April 1st, 1905, p. 852.

Looking to Power's view (as interpreted by Dr. Stevens) that the influence of a hospital "was most remarkable when the total admissions had not exceeded nine," it is not surprising to be told that "the same divergent views that exist as to the influence of the wind also exist as to whether the vicinal increase is greater when there are many or few cases," though on the whole it appears to Dr. Stevens that importance is attached to aggregation, and this being so the presumption is that Power, pinning his faith to nine or less, must be himself in a small minority. Also "even the supporters of aerial convection are disposed to limit this danger to acute cases." Having in this fashion set forth and criticised the views of the aerialists, Dr. Stevens hopes that in future the Local Government Board "will allow some relaxation of their previous rules and will be guided rather by the likelihood of precautionary regulations being strictly enforced than by isolation of the hospital—a matter often both costly and difficult." But it looks rather doubtful in what direction this likelihood of strict enforcement of regulations is to lead the Board, for in explaining hospital influence Dr. Stevens has previously declared that "so long as there are nurses and porters they will have their friends outside and all the regulations in the world will not keep them in." The unlooked-for conclusion would therefore appear to be that "likelihood" means not merely "unlikelihood" but actual impossibility, and that in order to minimise mischief from utterly inevitable infringement of regulations hospitals should be exceptionally well isolated and that the Board should "relax" its present rule by no longer sanctioning hospitals which have anything like 600 people within half a mile's reach of the rebellious nurses and porters.

The writing indeed is in places very slipshod, and better things in this direction might have been expected from an Oxford graduate in arts and medicine. In one of the passages we have quoted there seems an obvious slip in grammar. Referring to diagnosis (p. 64), he writes, "although the medical man in attendance may strongly suspect the disease he is unable to certify on the evidence that in his opinion it is small-pox and the ambulance authorities will not remove him unless a definite statement to this effect is made." But what good this vicarious removal of the medical man would do is not explained. The valuable information in the book and the gallant attempt to be fair-minded are somewhat frustrated by inattention to the literary requirements.

LIBRARY TABLE.

Handbook of Anatomy for Art Students. By ARTHUR THOMSON, M.A. Oxon., M.B. Edin., Professor of Human Anatomy in the University of Oxford; Professor of Anatomy, Royal Academy of Arts, London. Third edition. Oxford: At the Clarendon Press. 1906. Pp. 450 and index. Price 16*s.*—Professor Arthur Thomson's admirable Handbook of Anatomy for Art Students has now reached its third edition, a proof, if need be, that the book has been found useful by that class for whom it is written. So excellent was the book in its original form that much could not be done in future editions to improve it. In the present edition but very little has been added to the matter of the text, but several new illustrations have been included and the plates have been reproduced upon a much larger scale. In former editions the key plates applied solely to a male figure. In the present edition a photograph of a female figure in the same position as that of the male has been added. We can only repeat that every art student should possess this book and even ordinary students of anatomy will learn a great deal from a perusal of it.

Old Sea Chanties. Collected and arranged by JOHN BRADFORD and ARTHUR FAGGE. London: Metzler and Co. Price 1*s.*—The chanty is almost extinct and we are very glad that some few of these beautiful old melodies have been preserved by Mr. Bradford and Mr. Fagge. The tonality of the first chanty, "Haul on the Bowlin'," is somewhat uncertain and gives a curious effect to the ear, but it is a singularly fine melody. All the songs—there are eight of them—would be admirable for singing at smoking concerts and other festive gatherings. They can be had arranged for chorus and orchestra as well as for solo, and in this form will be found to be an admirable addition to the library of choral societies.

JOURNALS AND MAGAZINES.

West London Medical Journal.—In the April number are contained some papers of considerable interest. Dr. Neville T. Wood discusses the Treatment of Constipation and Colitis by Paraffins and Agar, the principle involved being the addition to the intestinal contents of fatty or other substances which are not digested. The method seems well worthy of trial in obstinate cases. Dr. J. A. Coutts treats of some points in Infantile Scurvy, calling attention to the advisability of surgical interference in some cases in order to prevent necrosis of bone following extensive subperiosteal hæmorrhage, and Dr. E. Furniss Potter and Mr. Richard Lake contribute practical articles on aural troubles.

The Caledonian Medical Journal (April).—The experience gained from our own errors is sometimes bought rather dearly; it is more satisfactory to learn from those of others. Mr. James L. Waters, in an interesting if discursive article, endeavours to put his experience as to errors in diagnosis at the service of his medical brethren who should profit by the hints given. Dr. Duncan Macdonald concludes his paper on the Prevention of Pulmonary Consumption in the West Highlands, noting as causes of infection the inhalation of tuberculous dust and of tuberculous matter directly expectorated, as well as the occurrence of cases due to living in houses, theoretically disinfected, which had been occupied by consumptives, and to wearing of the clothes or sleeping in the beds of such patients.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

"TABLOID" BRAND PASTILLES.

(BURROUGHS, WELLCOME, AND CO., SNOW-HILL BUILDINGS, LONDON, E.C.)

WE have received specimens of tabloid pastilles which are a great advance on the ordinary medicated demulcent jujube. They are transparent and the demulcent basis dissolves slowly in the mouth. They are neatly packed in waterproof paper and tin boxes. The list of tabloid brand pastilles comprises a plain glycerine preparation, glycerine with black currant, tannin, cocaine hydrochloride, codeine, benzoic acid compound, red gum, rhatany, and so forth. The tabloid brand pastilles have a diameter about that of a shilling and are about a quarter of an inch thick.

all recent work, the text is rarely burdened with references. This has the advantage of rendering the book more easily readable but the disadvantage of depriving us of a bibliography from which the original sources of information can be consulted.

Scientific Memoirs by Officers of the Medical and Sanitary Department of the Government of India on the Standardisation of Antityphoid Vaccine No. 21. By Captain GEORGE LAMB, M.D. Glasg., I.M.S., Director of the Pasteur Institute of India, and Captain W. H. C. FORSTER, M.D. Edin., D P.H Cantab., I.M.S. Calcutta: Office of the Superintendent of Government Printing, India. 1906. Pp. 15. Price 6 annas, or 7*d*.

THE authors truly state that vaccination against typhoid fever has now taken its place amongst the measures of preventive medicine, its achievement being principally due to the brilliant work of Wright. That success has crowned his efforts is certain from the facts (1) that three scientific committees successively convoked to examine into the matter have decided that the statistical evidence is sufficient to show that the incidence and case mortality are reduced by inoculation; and (2) that the Germans have adopted it in the case of troops proceeding on foreign service to Africa. One of the most important problems, however, with regard to this measure is the elaboration of some method of standardisation. This problem is considered in the memoir under review.

The authors first demonstrate the various methods by which the antityphoid vaccine may be prepared, resulting in the production of "broth vaccine," "agar vaccine," or "filtrate vaccine." They then proceed to the question of standardisation and tell us what is meant by the term, using the definition of Wright for this purpose—namely, "Standardisation involves on the one hand the determination of the amount of immunising element contained in a standard volume of the vaccine material; on the other hand, the adjustment of the dose administered to the resisting powers of the man or animal submitted to the inoculation." The first problems to be settled are the nature of the immunising element of the vaccine and the manner in which it accomplishes its object. The immunity induced by antityphoid vaccination is, in the main, a bactericidal immunity due to an increased power of the individual to kill the typhoid bacteria by his body fluids, which increased power is again due to an increase in the specific amboceptor or immune body in the body fluids. The body also after inoculation probably acquires a habit of producing these protective substances on a stimulus of a much slighter nature than before the inoculation; in addition there is no evidence of an antitoxic immunity. The power of any vaccine to increase the quantity of immune substance in the body fluids depends upon the number and avidity of the receptors contained in a unit quantity of the vaccine, and therefore, when the proportion of free immune body which can be fixed by the receptors of the vaccine without danger to the organism can be estimated, the problem of determining the optimum dose of an antityphoid vaccine will be solved. Towards this end therefore must first be established a method of measuring the receptor content of any vaccine, which is the true basis of standardisation of all antityphoid vaccines. The authors examine in this light the methods previously used and point out the various objections that can be raised to them. They then state that in order to comply with the first proposition of the definition of standardisation above stated the absolute receptor content of a vaccine must be determined. Next they show that the adjustment of the dose of any antityphoid vaccine to the average resisting powers of man can only be estimated by direct experiment, and such an experiment is already in progress under the direction of Lieutenant-Colonel W. B. Leishman. The authors conclude their interesting memoir by detailing a method which they have elaborated with the view of standardising every vaccine used against a standard vaccine obtained as the result of this direct experiment. The technique is duly set forth and as the result of their researches they conclude that the broth vaccines possess three and four times the bactericidal power of the filtrate vaccines.

This volume of the Scientific Memoirs, though short, contains an immense amount of intricate work and reflects the greatest credit on the authors.

Small-pox, its Dissemination and Prevention: Thesis for Degree of Doctor of Medicine. By FRANCIS JOSEPH STEVENS, M.A., M.D. Oxon., M.R.C.S. Eng., D.P.H. R.C P.S. Eng., sometime Exhibitioner of Exeter College, Oxford; Medical Officer of Health to the Metropolitan Borough of Camberwell, &c. London: Henry Frowde. 1906. Small 8vo, pp. 128. Price 2*s*. 6*d*. net.

Dr. Stevens's graduation thesis consists of a short introduction and three chapters, entitled "I. The Dissemination of Small-pox"; "II. Aerial Convection"; and "III. The Prevention of Small-pox, Inoculation and Vaccination, Vagrancy." Chapter I. begins by a criticism of the view that small-pox is one of the most infectious of diseases. A variety of instances are quoted in which exposure to infection did not result in attack, as, for example, an out-patient at the Edinburgh Royal Infirmary with the rash fully out who yet caused no extension of the disease, and a recently confined woman suffering from unrecognised variola in Camberwell who held a constant levee but infected "only eight of her neighbours." Notwithstanding all such evidences of slightness of infectivity, especially of mild cases, Dr. Stevens argues that it is possible that in presence of a mild type of epidemic, unrecognised cases may spread the infection far and wide, and he says that there can be little doubt that the perambulation of mild cases is the chief cause of the dissemination of small-pox in London. Excepting as to their clothing, he condemns the view that "contacts" are a danger to the community, a view which, he says, has apparently been advocated in all seriousness by Littlejohn and is supported by Priestley and in Leicester, where the so-called system "includes this quarantine for 14 days as one of its regulations."

The reader turns to the chapter on Aerial Convection with some interest to learn whether the author holds that such cases as he has instanced of the frequent escape of "contacts" from infection, especially from mild cases, tend to support, by exclusion, the theory of aerial dissemination and to discredit the view that hospital influence is always to be explained by intercourse. The answer is in the negative; Dr. Stevens here holds that intercourse is the sole explanation. Concerning the influence of aggregation of cases, he says that Power at first arrived at the conclusion that recent epidemics had shown a nearly constant relation between the amount of hospital admissions—especially a sudden increase in the number of acute cases—and the prevalence of small-pox, but that in a later report in 1884 "he comments on a new factor" which had appeared —namely, "that the excess of small-pox incidence on a neighbourhood was most remarkable when the total admissions to hospital had not exceeded nine." Regarding the influence of wind and weather Dr. Stevens states that there is a somewhat startling difference in the conclusions of those who hold the aerial theory, Power and McVail pinning their faith to calm weather and fogs, while other observers (apparently Buchanan and Thresh, for example) "contend a wind much more readily favours the conveyance of the poison." Dr. Stevens's own conclusion regarding the manner in which this subject has been approached by those from whom he differs is that "indeed, from the diversity of views on the subject of weather influence it would seem as if those existing at the time of the supposed aerial

THE LANCET.

LONDON: SATURDAY, MAY 5, 1906.

The Administration of the Vaccination Acts.

THE recent debate in the House of Commons upon the subject of what is erroneously termed "compulsory" vaccination was not an altogether edifying spectacle, more especially as those who could have enlightened the House as to the facts and as to the administration of the statutes were either absent or unable to speak. Mr. LUPTON's proposal that "vaccination ought no longer to be obligatory on those who regard it as useless and dangerous" was a far from exciting, or even interesting, topic for debate, seeing that since the introduction of the Act of 1898 there is absolutely no compulsion upon those who can satisfy the magistrate that they have a conscientious objection to vaccination. That this is the case is shown by the dying out of the demonstrations which were not uncommon prior to 1898 and the absence of any unfomented and spontaneous feeling against the existing provisions. In the interests of truth and equitable legislation it is much to be regretted that neither Mr. WALTER LONG nor Sir WALTER FOSTER, both of whom are familiar with all the facts, were afforded an opportunity of bringing before the House the excellent results, in the country generally, of the working of the present Act, while we cannot but express our regret that the medical Members of the House did not evince some active interest in a subject which touches so deeply the health of the people.

In these circumstances the speech by Mr. BURNS must, we think, be regarded as a thoroughly statesmanlike pronouncement. Although we may have reason to differ sharply from him in the future we take this opportunity of congratulating him upon the administrative judgment which, as practically the Minister of Public Health, he displayed on this occasion. Mr. BURNS is, all must recognise, in a somewhat difficult position in matters which in their equitable adjustment call for scientific knowledge and an entire absence of passion, but his attitude has up to the present indicated a desire to master his subjects and to deal with them not solely for the benefit of the ignorant. He has obviously no sympathy with the loafer and has no desire to see the population replenished solely from the unfit. But he has, we know, the keenest sympathy with the fighter and with those who by their efforts have raised themselves from the mass. He has told the world in the brief autobiography contained in the last edition of "Who's Who" that he "came into the world with a struggle, struggling now, and prospects of continuing it," an intelligible if elliptical assertion which would indicate that he is not anxious to engender in those who work with their hands that helplessness and lack of self-reliance which promotes physical and moral degeneration. We interpret Mr. BURNS's desire to remove the administration of the measure from the hands of the Poor-law authorities to one or another of the health authorities—i.e., the district councils or the county councils (or, perhaps, he would like to see both councils play their part)—as an intention to increase general sanitary efficiency, and we see no reason why the medical profession should not so regard it. We wish to see less of that misplaced emotionalism which so often characterises the proceedings of boards of guardians when dealing with questions which relate rather to public health than to charity. We much wish that the figures had been furnished during the debate which show that there is year by year a decreasing number of persons who have failed to comply with the very lenient provisions of the present vaccination statutes by obtaining either the vaccination of their children or a certificate of conscientious objection. This fact is doubtless appreciated by Mr. BURNS and he will perhaps, in justice to those who have administered the Act, make it public when a fitting opportunity arises. As an instance of the remarkable change wrought in some places by the measure of 1898, which we have never pretended to regard as absolutely perfect, we may briefly refer to the position of affairs in the borough of Halifax, for the figures concerning which we are indebted to Dr. ARTHUR DRURY, the public vaccinator. Dr. DRURY tells us that some years ago "organised opposition was in great force, many demonstrations were held against vaccination. ...... A generation of parents had sprung up who knew nothing of vaccination from their own personal observation but who had been terrorised by the alarming statements and misrepresentations made by leading and active anti-vaccinationists." The annual number of primary vaccinations for the four years preceding 1898 was 203, 202, 158, and 199; those for the last four years (1902-05) were 1053, 2193, 2430, and 2816, a result which has been attained, we are informed, "without precipitating any hostile demonstration, and organised opposition, if it exists, is dormant. A very small percentage of prosecutions have actually taken place. Of the comparatively few conscientious objections which have been applied for it is a fact that in a number of cases vaccination has been since resorted to, although exemptions have been previously obtained for the same children." Halifax has, in fact, defeated a motion for the repeal of the Vaccination Acts, as in many families where previously objection had been strong the vaccination of the youngest child has been followed by a voluntary request from the parent for the vaccination of the rest of the children. As Dr. DRURY remarks, "The provisions of the new Act have restored confidence in the public mind in a manner which could not have been attained under the old and less costly regulations."

Mr. BURNS, in the course of the inquiry which he has promised, will doubtless have regard to this experience of *Halifax*, recently a stronghold of the antivaccinationists, which is in no sense unique, and we feel quite satisfied that his inquiry will be a thorough and an eminently fair one. He reminded the House in the course of his speech that vaccination is not now compulsory, saying that

BISQUIT'S OWN BRANDY.

(AGENCY: MERRITT, BIRD, AND CO., 11, HART-STREET, MARK-LANE, LONDON, E.C.)

THIS is excellent brandy, with a delicate elegant flavour characteristic of fine Cognac brandy. We can well believe the statement that it is 14 years old and that it is a genuine distillation of grape-wine. The results of analysis are in accordance with those given by a genuine Cognac brandy. The ethers amounted to 143 grammes per hectolitre of absolute alcohol present, while the total secondary products amounted to 314·00 grammes. The furfural amounted to exactly one gramme, a relatively small figure, indicating elimination of this substance by age. This brandy is clearly of excellent quality.

SAJODIN.

(THE BAYER CO., LIMITED, 19, ST. DUNSTAN'S-HILL, LONDON, E.C.)

Sajodin is described as "a perfectly tasteless and thoroughly efficient substitute for potassium iodide, free from secondary effects." It is the calcium salt of mono-iodo-behenic acid and has the composition represented by the formula $CaC_{22}H_{42}O_2I_2$. It contains 26 per cent. of iodine. The formula of behenic acid is $C_{22}H_{44}O_2$ and it occurs as a glyceride in oil of ben. In some German clinical reports sajodin is mentioned as an excellent therapeutic agent in tertiary syphilis, bronchial asthma, and arterio-sclerosis. Sajodin is a white powder insoluble in water and yields an abundance of iodine vapour on heating or when treated with nitric acid.

YAGHOURT (CURDLED MILK).

(A. E. EFSTRATIOU, 38, CHANDOS-STREET, ST. MARTIN'S-PLACE, LONDON, W.C.)

In the Paris notes in THE LANCET of Feb. 20th, 1904, p. 546, appeared an account of the milk preparation called Yaghourt which is consumed so largely in Turkey. In that country there is a great consumption of the milk of the buffalo, the common cow, the goat, and the ewe, but it is hardly ever used in a natural state. According to a paper read at the meeting of the Academy of Medicine the milk is kept at a moderate heat until its bulk is considerably reduced. After slow cooling the milk is treated with a ferment taken from the previous day's supply. In a few hours a curd forms which is called Yaghourt. The preparation is preferred to milk and it has a pleasant clean acid taste and is, of course, nutritious. Yaghourt, as well as many other oriental dishes, may be obtained at the above address, where they are prepared by a *special pastrycook who hails from Constantinople.* We made an analysis of one sample and the results showed that there were present 83·50 per cent. of moisture and 16·50 per cent. of dry solid matters containing the mineral, proteid, and fatty matters of the milk. The total acidity calculated as lactic acid amounted to 1·3 per cent. Yaghourt is thus a more concentrated preparation than ordinary milk and it is much more digestible. In the Paris note referred to it is stated that not only has yaghourt the nutritive value of milk in a small bulk but it also possesses a diuretic property which is useful in heart disease, in dropsy, and in the eclampsia of pregnancy. We also examined a nutritious sweetmeat made by the same Turkish pastrycook which is said to be made with the flesh of tender chickens, with milk, cornflour, ground rice, and sugar. This contained 74 per cent. of moisture, while the solid matters consisted of about 15 per cent. of proteid. There can be no doubt, therefore, that this preparation known as "taouk-oxou" represents a very nourishing article of food which, moreover, is very palatable.

ADALA FOOD.

(ADALA CO., 116 AND 117, HOLBORN, LONDON, E.C.)

Adala food is stated to be prepared in Norway from choice pieces of Adala Kap fish caught in the Polar seas. Most people entertain a prejudice against fish preserved in tins, but we find that this fish food was not only in an excellent state of preservation but showed absolutely no trace of metallic contamination. Moreover, the flavour of the fish prepared in the way directed was quite good. We understand that the fish soon after it is caught is put into tins and then sterilised; it makes an excellent and cheap nourishing food.

DRY GIN.

(J. & W. NICHOLSON AND CO., LIMITED, 195, ST. JOHN-STREET, CLERKENWELL, LONDON, E.C.)

The chief merit of this spirit consists in its remarkable purity; it is practically free from acidity and extractives, the latter amounting to only 0·04 per cent. As to secondary products, only ethers occurred in important quantity, while there were mere traces of higher alcohols and aldehydes and absolutely no furfural at all. The flavour of the spirit is characteristically dry, certainly as regards sugar, but it has that sweetness peculiar to gin of the finest description. Gin, as is well known, possesses diuretic properties and is one of the most useful stimulants in many pathological conditions, being absorbed and eliminated from the system with great rapidity.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 3rd, 1828

ON THE CAUSE OF THE DIFFERENCE IN THE STRENGTH OF THE RIGHT AND LEFT ARMS.

M. Lecomte lately read before the Institute of France, a paper on the superiority of strength of the right over the left arm. This physician thinks the difference owing to the position of the fœtus in the womb during the latter months of pregnancy. In by far the larger number of cases, the position of the child is such, that its left shoulder, arm, and the whole of the left side, are pressed against the bones of the pelvis; from this pressure, a contraction of the blood-vessels (a kind of atrophy of the left sanguineous system) ensues. The weakness of the left side, then, arises from this congenital *disposition.* According to M. Lecomte, it is the right side which is the weakest, when the child is placed in the uterus in the contrary direction, which accounts for those who are left handed.

WE beg to direct the attention of the reader to the following valuable communication from Dr. BUSHE, in which it will be seen that *another cure* of carotid aneurism has been effected by tying the vessels on the distal side of the tumour,

A Case where the Right Carotid Artery was successfully Tied. on the distal side of a large Aneurismal Tumour. By GEORGE BUSHE, M.D., of the Royal College of Surgeons in Ireland, and Assistant Surgeon to the Forces.[1] Some person, signing himself "A Surgeon of Chatham," *sent a superficial account* of this case to the Editor of THE LANCET, written ten days after the operation, in which he stated, that he was induced to do so, fearing that the despotism which reigns in the Medical Department of the Army, might prevent my tendering it to the public; therefore, I feel compelled to inform that Gentleman, that if he will look to the records of medicine and surgery, he will find, that some of our military medical officers have, since the appointment of the present Director General, by the publication of their experience, contributed not a little to the improvement of our art, and that so far from there being a wish in the department to crush merit, every opportunity is afforded the most junior officer to advance himself (as far as military regulations will permit) by laudable exertions.[2]

EPIGRAM[3]

*On the Patient who suddenly decamped from Guy's Hospital, and passed over to St. Thomas's.**

Rash, thoughtless man! ah, whither dost thou fly!
If death appal thee, why *such haste to die?*

Bath, April 28th, 1828.

---

[1] Here follows the communication, which occupies five columns of THE LANCET and has not been transcribed.

[2] See "Looking Back," in THE LANCET, Sept. 30th, 1905, p. 971.

[3] See "Looking Back," in THE LANCET, April 21st, 1906, p. 1118.

* Vide LANCET, No. 241, p. 49.

The experts are sworn, unless this formality be waived by common consent of the litigants, and they hold a session at which the physician in charge of the case is expected to attend, and at which both the employer and the injured person are represented. They listen to all that can be told them, examine all certificates which have been given during the progress of the case, make every examination of the patient which seems to them to be required, and appeal at every step to the physician in charge and to the litigants as to whether there is anything else which they should do. They may make more than one visit, either to avoid fatiguing the patient by prolonged examination or in order to clear up any doubtful point, and they then privately settle their report and present it to the presiding authority concerned, describing the injury and giving their considered opinion as to the actual state and the probable future of the sufferer. Upon the materials thus supplied the decision of the tribunal will be founded; and the costs of the inquiry are limited by a legal tariff of the fees payable to all who are concerned.

A considerable time will probably elapse before an equally effective measure of assessing the results of accidents will be introduced into this country, and our "experts" will probably long continue their present practice of delivering independent and sometimes widely different opinions in the witness-box, opinions between which an absolutely ignorant body of jurymen must decide according to their several degrees of illumination. The results of the French practice may none the less be of great value to medical men among ourselves; and the work of Dr. VIBERT is well worthy of careful consideration and perusal. He deals at considerable length with what he describes as the neurasthenic and hystero-neurasthenic types of disease following concussion, and brings together a number of valuable reports of illustrative cases. It is noteworthy that he attaches but small importance to simulation as an element in these cases and that he regards undue readiness to suspect simulation as a characteristic of practitioners who are but moderately skilled in the investigation of nervous maladies. He also cites many cases illustrative of the amount of damage which may be inflicted by severe concussions upon organs and structures which have not been wounded in the common acceptation of the word, but which may nevertheless have undergone considerable interstitial injury, rupture of fine blood-vessels, destruction of cells, and so forth. A sudden shock communicated to the body projects the organs contained in its cavities against the walls of those cavities, and the resulting conflict between opposing forces may be productive of "lesions of commotion" which are often extremely grave. In post-mortem examinations of persons who have died comatose after injuries to the head it has often happened that only very slight injuries to the brain were discoverable by the naked eye and that general shock to the organ has appeared to be the cause of death. In some instances the individual, after an injury to the head, immediately loses consciousness and remains in that condition for a day or two, after which he may be the subject of a degree of mental confusion or even of delirium for some days more. Then the brain troubles disappear and in a short time recovery will be definite and complete. Others may sustain a similar and apparently less serious injury attended by less severe initial symptoms, but these may be followed by cerebral disorders producing permanent disability. In the presence of a recent injury to the head, the practitioner should never forget that the first symptoms afford no measure of the real gravity of the lesions, and furnish no grounds for a definite prognosis or diagnosis. In relation to the general subject of traumatic neuroses, Dr. VIBERT gives a number of valuable illustrative cases, in most of which there was a gradual but slow tendency towards recovery, and he discusses the diagnosis of such cases with great lucidity, dwelling especially upon permanent quickening of the pulse as a symptom indicating the reality of the affection. Headaches, disturbed rest with dreaming, occasional attacks of giddiness, diminished power of attention, and impairment of memory, are also described as usual symptoms, and all these will sometimes lead on to permanent disablement and obvious nervous degeneration. Dr. VIBERT'S histories are calculated to teach a lesson of caution to the practitioner and to emphasise the value of reticence as opposed to too confident prediction. They render it obvious that the actual amount and character of the injury done to the nervous centres by concussion cannot be estimated by any methods of examination which are available at or near the time when the shock itself was received.

The Paris Medical Journal.

THE movement for a better understanding and more intimate relations between France and England, known as the *entente cordiale*, continues to manifest itself in new forms. Of these not the least important is the closer intimacy which has sprung up between our French brethren and ourselves. The publication of a new periodical, the *Paris Medical Journal*, a monthly review of French medicine in English, is not an event which appeals only to medical men, only to journalists, or even only to Frenchmen and Englishmen. It is a sign that two of the leading literary and scientific forces of civilisation have recognised that science knows no national boundaries. The immediate design of the new journal is to make more widely known the work of the members of the great Paris school who are so well carrying on the torch handed to them by TROUSSEAU, PASTEUR, and CHARCOT, but at the same time it will not neglect the provincial schools. Each month will be reviewed the important communications to the Académie de Médecine and to the other societies and the articles of interest in the leading French journals and one of the French hospitals and watering-places will be described. In no capital in the world is the task undertaken so easy, for in none is there such centralisation. In Paris there is not, as with us, any confused overlapping of medical societies. There are one chief society and one chief journal for each special branch of medicine. Thus, the authoritative opinion of French surgery is to be found in the discussions of the Société de Chirurgie, while French therapeutics and medical pathology are well represented in the reports of the Société Médicale des Hôpitaux de Paris, which consists entirely of the hospital physicians. The *Paris Medical Journal* is edited by Dr. A. A. WARDEN, physician to the Hertford British Hospital, and Dr. E. L. GROS. The editorial committee the only step necessary to remove, as it were, the last vestige of compulsion is to prevent the browbeating in which certain magistrates are prone to indulge. For our part, we would take the fact of the parent's presence before a magistrate, coupled with a statement that he had a conscientious objection to vaccination, as meriting the certificate of exemption for which he seeks. Discussions upon "conscience" between the educated and the uneducated are neither fair nor edifying. But we would insist upon the attendance of the parent before the magistrate. Those whose conscience involves a danger to their fellow subjects and, perhaps, enormous financial loss to the community in which they live, may reasonably be called upon to make some little sacrifice as regards time. The cost of the certificate should, we think, be purely nominal. With reference to the expense of administering the Vaccination Acts and as to the age at which vaccination might be carried out, we shall have more to say on a future occasion, but we trust that Mr. BURNS will extend his proposed investigation so as to bring out clearly, for purposes of comparison, the cost of small-pox outbreaks to local authorities and to the trade of towns in which such outbreaks have occurred, and that he will have regard to the cost to the community of the provision of the separate small-pox hospitals necessitated by our present unprotected condition. Such hospitals might be practically discontinued had we as a people the common-sense and moral force of Germany, which is so far the only nation to succeed by vaccination and revaccination in holding small-pox in check. All these facts and the literature thereto are at the disposal of Mr. BURNS, and his excellent medical department may be trusted to give him expert assistance.

◆

Industrial Accidents: A Lesson from France.

THERE is a Bill at the present moment before the House of Commons having for its purpose the amendment and consolidation of the law in respect of the compensation of workmen for injuries suffered in the course of their employment.[1] The Bill does not give complete satisfaction, and we recommend to our legislators the perusal of a book lately published by Dr. VIBERT on the character, importance, and consequences of accidents occurring to workmen in the course of their occupations.[2] This work not only affords a new and interesting illustration of the general principle laid down by STERNE—that they "do these things better in France"—but also contains a large amount of suggestion calculated to be eminently useful to the many practitioners in this country who may be called upon to treat injuries to workpeople of a kind calling for compensation from their employers. The law upon this subject in France is of more recent date than that in England, but is already much more systematised as regards its application, and our neighbours have thoroughly recognised the importance of the scientific "expert" in assisting the legal tribunals in their work of equitable administration. The English Employers' Liability Act dates from 1880 and its administration leaves the settlement of disputed questions to the discretion of a jury, aided by such lights as the medical witnesses called respectively by the plaintiff and the defendant are able to throw upon the case; but the French methods of procedure, as described by Dr. VIBERT, appear far better calculated to secure substantial justice at a minimum of cost. The law was enacted in 1898 and under its provisions the workman who sustains an accident in the course of his occupation is treated by the physician of his own choice and at the expense of his employer, whose liabilities on this account are limited by a settled scale of fees. During incapacity from injury, and until he is either cured or left in some settled and permanent state of disability, the workman receives half-pay after the first five days; and he is compensated for permanent disability or impairment of usefulness in accordance with an elaborate scale in which almost every possible consequence of an accident is provided for and is assessed at a percentage upon the original value of the workman. The law makes provision for giving proper notices to all the persons affected and any differences concerning temporary payments are subject to the decision of a magistrate. When an injury has left any degree or kind of permanent incapacity, and the sufferer and the employer are able to agree touching the amount of the indemnity, their agreement is ratified by the president of the civil tribunal and is thereafter unassailable, but if they are unable to agree the case is submitted to the tribunal for adjudication and may be carried to higher courts by appeal. The first decision may also be reconsidered, after the lapse of three years, at the instance of either party, on the ground that the state of the sufferer has been shown by time to be either better or worse than was originally supposed.

An "accident of labour" is defined to be something sudden and unexpected, or manifestly abnormal in its occurrence, and therefore does not include what are described as "professional" maladies, more or less incidental to the industry pursued, such, for example, as lead poisoning in the case of painters or pottery workers. Dr. VIBERT quotes with approval the definition of Dr. THOINOT, which makes an accident comprise "every external wound, every surgical or medical lesion, every psychical nervous disturbance (with or without associated bodily lesion) resulting from the sudden effect of external violence intervening during work or in consequence of work, and every internal lesion produced by a violent effort in the course of work." He further points out that the term external violence must be made to include the effects of heat and cold, as in cases of sunstroke or of congelation. In any case in which the question at issue cannot be satisfactorily determined, either by the magistrate immediately after the accident, by the president of a tribunal called upon to ratify an agreement, by the civil tribunal, or by a court of appeal, recourse must be had to the advice of nominated experts, and for this purpose any practitioners who have attended the patient, as well as any who may be permanently employed either by the industrial undertaking in which the accident occurred, or by any assurance office concerned, are absolutely ineligible.

aim of the committees was to get a medical man as cheap as possible. The remuneration of the surgeon was often less than it might or ought to be. He was hampered by restrictions as to the methods of carrying on his work which were annoying and sometimes humiliating to a sensitive man. As for remedies, the operations of the medical aid associations should be confined as far as possible to members of friendly societies and their families. They should secure the services of a capable gentleman for a medical officer and having found that he was suitable he should be given the full confidence of the committee, his salary should be liberal, and nothing should be done to make him feel that he was a servant. They should not worry him with the details of petty and paltry complaints and they should by every means in their power endeavour to raise the status of their medical officers so as to make the position one that would be sought after by capable members of the profession. The meeting agreed that Mr. Webb's paper should be printed and circulated. No one, be he medical man or layman, who has read the papers which we have published under the heading of "Battle of the Clubs" can doubt that Mr. Webb's estimate of the way in which medical men have been occasionally treated is perfectly fair. If medical societies would act upon the lines which have been so well laid down by Mr. Webb the "Battle of the Clubs" might soon become as much a matter of history as that of Waterloo.

THE UNSEASONABLE APRIL.

RARELY has the month of April proved so treacherous and trying as the one which has just elapsed. This is more especially true of the southern half of England, where the changes of temperature were the most frequent and sudden, the diurnal range the greatest, and the penetrating property of the easterly and northerly winds the keenest. There has, perhaps, never been a month, even in the spring when a spell of Polar winds is one of the only certainties of the British climate, that the current of air over these islands has been so persistently from a cold, dry quarter. Until quite the end of the month there were only three days on which the wind in London and the south and south-east of England generally was not blowing from some point between north and east, while during the greater part of the time not a drop of rain moistened the parched soil of the country or flushed the drains and sewers of the towns. Regarded as a whole the temperature was not many degrees below the normal, the warmth of the earlier part of the period counterbalancing to a considerable extent the cold of the last fortnight. Happily, the month was unusually sunny throughout the whole kingdom and it is entirely due to this important fact that the temperature on many of the days when the easterly wind was keenest rose above the ordinary level for January. The sunshine was, indeed, the one redeeming feature of the month and did much to counteract the evil of the piercing winds. In Westminster and a few other localities the duration of sunshine was greater than that of any other April since the recording instruments have been in use—that is, since 1881. The nearest approach to the present record occurred during the droughty and very warm April of 1893. From the point of view of the meteorologist last month was one of unusual interest as a striking illustration of the persistency of a certain type of weather during a long period. The Polar winds were, of course, the direct result of high atmospheric pressure in the north and west and of low in the south and south-east. But why the anti-cyclone which generally lies in the neighbourhood of the Azores and frequently extends to the Spanish Peninsula and France should have moved bodily or sent out an arm so far north as Ireland and the west of Scotland to act as a barrier against the passage of the [illegible]lonic disturbances from the Atlantic across Ireland to Scandinavia, is beyond the power of the most learned meteorologists of to-day to determine. Below will be found the mean temperature and the total duration of sunshine for the month, together with the difference from the average of several selected stations:—

—	Mean temperature.	Difference from average.	Sunshine (hours).	Difference from average.

THE INTER-RELATION OF EDUCATION AND INFANT MORTALITY.

IT is interesting, and should be equally instructive, to glance occasionally at the reasons given—in many cases in humble, apologetic tones—for the high rate of infantile mortality that disgraces so many of our towns. A discussion took place recently at a meeting of the town council of Ashton-under-Lyne illustrative of various views. The infantile death-rate in a part of one of the wards was very high. The mayor said that a seventh of the deaths were of illegitimate children, only one of whom lived to be seven months old. There can be no question that these waifs are very bad lives. No one wants them. They are in the way; they meet with no welcome from the mother's relatives and the mother herself, if still retaining some traces of modesty, is ashamed of her offspring, and so natural affection, like the baby itself, stands a poor chance of long survival. The mayor contended that this state of things was due not to insanitary property but to social and industrial evils that should be checked. He thought that after the way boys and girls loafed about the streets such a report should cause no surprise. One gentleman attached more importance to many of the houses being absolutely "unfit for human habitation"; he thought that many of those present would not stable their animals in such places. Another expressed the opinion that the ignorance of the mothers as to feeding the infants was the greatest evil. Of course, all were right in attaching importance to what they considered chief factors in the case, but all wrong in taking too limited a survey of the difficulties under which the children of the poor in manufacturing towns begin the first twelvemonth's struggle for existence. The dwellings are unhealthy, damp, and ill ventilated in too many cases, occupied by dirty, ignorant people, at the best careless of the lives entrusted to them, and often glad enough to see those lives surely wasting away. Even without attributing sinister motives the appalling and disgraceful ignorance, left after more than 30 years' compulsory education, of everything as to the feeding and bringing up of an infant is sufficient to insure a high death-rate. The responsibility of this must fall in great part on the school authorities, being another proof of the necessity that the schoolmaster, the medical man, and the sanitarian are jointly concerned in the development of all sound educational schemes. In his recent report on the health of the borough of Bacup Dr. J. Brown says that the infant mortality is satisfactory "for a manufacturing town, but it ought to be further reduced." This seems a little contradictory, but no doubt means that however good the position may be efforts should consists of Dr. DEBOVE, professor of clinical medicine, Beaujon Hospital; Dr. DÉJERINE, professor of nervous diseases, Salpêtrière Hospital; Dr. DIEULAFOY, professor of clinical medicine, Hôtel Dieu; Dr. PINARD, professor of obstetrics, Clinique Baudelocque; Dr. POZZI, professor of gynæcology, Broca Hospital; Dr. ROBIN, professor of therapeutics, Beaujon Hospital; Dr. TERRIER, professor of clinical surgery, La Pitié Hospital; Dr. BROCQ, dermatologist to the St. Louis Hospital; and Dr. COMBY, physician to the Hôpital des Enfants Malades. Such a staff is a guarantee of good work and the first number, which lies before us, is excellent both in form and matter. The qualities of lucidity, conciseness, and precision are almost imposed on a writer in French by the qualities of the language, which is adapted to the purposes of science more admirably than our own tongue with its greater range of choice and distinctly looser methods of expression. For English medical writers the virtues which we have called essentially French are an attainment and, unfortunately, a rare attainment; but, as might be expected, they are not wanting in this English journal produced in a French atmosphere. There is an important article by Professor A. CHANTEMESSE on "Five Years' Experience with Anti-typhoid Serum." He makes out a strong case in favour of this treatment. In 3595 cases of typhoid fever treated in 14 of the Paris hospitals there was a mortality of 17·3 per cent. In the hospital "Bastion 29" under the same treatment with the exception of the use of anti-typhoid serum there were only 27 deaths in 712 cases, a mortality of 3·7 per cent. The serum caused a rapid disappearance of the diarrhœa, headache, and other toxic symptoms. Under the head of "Paris Cliniques" are a series of brief but comprehensive clinical lectures of considerable interest. The subjects are "Bile-duct Lithiasis" (Dr. CHAUFFARD); "Choledochotomy" (M. QUÉNU); "Prognosis in Acute Sero-fibrinous Pleurisy" (Dr. BARTH); "Recurrence of Vesical Papillomata" (Dr. LEGUEU); "Stovaine *v.* Cocaine" (Professor RECLUS); "Chronic Tertiary Lesions and the Value of Mercury" (Professor DIEULAFOY); and "Cerebro-spinal Meningitis" (Dr. WIDAL). There are a biographical sketch and portrait of Professor DEBOVE, Dean of the Faculty of Medicine, the first of a series of the kind. We welcome the appearance of the *Paris Medical Journal* and trust that it will have a useful career.

Annotations.

"Ne quid nimis."

THE METHOD OF PHOTOGRAPHING THE DEAD FOR PURPOSES OF IDENTIFICATION.

AT two inquests held last week on the bodies of persons unknown the coroner commented at some length on the very unsatisfactory character of the photographs of the corpses prepared by the police authorities and suggested that means ought to be taken to make such photographs more like the individuals when alive and therefore more useful for purposes of identification. The question raised by these criticisms, though it is obviously of some practical importance, does not seem to have received much attention from medico-legal writers in this country and the bulk of the literature dealing with it is of foreign origin. One of the latest and most valuable contributions to its study is a paper by Dr. Minovici which appeared in the *Archives d'Anthropologie Criminelle* of Nov. 15th, 1904. The writer, who is director of the Medico-Legal Institute of Bucharest, gives in this paper a detailed account of the apparatus which he employs for posing the body and of the methods to which he has recourse for restoring the appearance of vitality to the features, his observations on this latter point being of special interest. One of the most serious difficulties in post-mortem photography is due, as is well known, to the loss of the brilliancy of the eyes, which has a large part in determining the characteristic expression of the individual. It has been usual to deal with this difficulty by the method suggested by Dr. Gosse[1] of applying compresses to the eyes, but Dr. Minovici has found that much better results may be obtained by the use of artificial eyes, dark or light, according to the colour of the individual's iris. A natural appearance can be given to the orbital opening by introducing beneath the lids an extemporised speculum of lead foil or by fixing the upper lid to the ball of the eye by means of a fine pin. The jaws can be drawn together with thread and by appropriate arrangements of pins various emotional expressions can be given to the face. Even in cases where putrefactive changes have occurred, if there has been no actual loss of substance, the features can be in a large measure restored if the gases in the areolar tissues are evacuated through suitable incisions in the scalp and in the buccal mucous membrane. By the application of these methods in a case where the body had been immersed in water for six weeks Dr. Minovici succeeded in getting a photograph sufficiently life-like to establish the individual's identity. Photographs showing the successive stages in the preparation of the body in this case are reproduced in the paper and give a striking illustration of the value of Dr. Minovici's ingenious artifices.

THE FRIENDLY SOCIETIES MEDICAL ALLIANCE: AN INTERESTING PAPER.

THE twenty-seventh annual conference of the above-mentioned organisation was held at Cambridge on April 16th. The Medical Alliance is a union of medical societies belonging to the friendly societies of the country and, as might be expected, most of the discussions at the congress had to do with the relation of medical aid associations towards their medical men. Some of the speakers showed that they were not very well acquainted with the duties of the General Medical Council and to the relation in which this body stands towards the medical profession. One speaker, for instance, referring to the difficulties which have lately arisen in Sheffield between the medical men and the Medical Aid Association of the Friendly Societies, is reported as saying that the "local body," which we suppose means the local practitioners, "in Sheffield appeared to be a branch of the General Medical Council." The most notable feature of the meeting from our point of view was a paper entitled "One of Our Difficulties," read by Bro. H. R. Webb of Banbury. Mr. Webb stated that the medical officer question was possibly the greatest difficulty that their association had to face and that members of the medical profession in many ways showed their want of sympathy with the friendly societies medical aid organisations. He then went on to inform his audience that in his opinion there were reasons for that which were more or less justifiable from the point of view of the profession and he thought that some of the causes of the trouble might be found to rest with medical associations and their management in the past. When medical aid associations were established the were found in the spleen, the lungs, and in the bone marrow, but not in the liver and kidneys. The cultural and staining reactions of the diplococcus were carefully studied and it was identified as the Fränkel-Weichselbaum pneumococcus, this conclusion being confirmed by inoculation experiments. The explanation offered of the frequency of such joint infections in infants is the peculiar structure and vascular arrangements of the bony rudiments of the joints, for, as shown by Neumann, the capillaries of the bone marrow in infants are of larger calibre than the smallest arteries, whereby the blood current is rendered extremely slow and the deposition of infective organisms in the tissues is favoured. The clinical features of the condition are described as being somewhat characteristic. The skin, especially of the face, is usually pale in spite of the fever, which is usually irregular; the temperature fluctuating between 37° and 40° C. There may be little or no disturbance of the appetite or digestion and the child may sleep well. This condition, as previously noted by Mr. Dudgeon and Dr. Branson, is somewhat suggestive and Dr. Herzog agrees with their description. The local condition is that of marked swelling and œdema around one of the larger joints, often involving almost the whole limb. There are tenderness on pressure and often increased heat but there is as a rule no circumscribed redness and this is an important distinguishing feature between pneumococcic and other forms of arthritis. In rare cases there may be an abnormal mobility of the joint. The pus when obtained by puncture of the joint is found to be non-offensive, of creamy consistence, greenish-yellow in colour, and frequently deposits threads of fibrin. The diagnosis of the condition is as a rule not difficult and can readily be confirmed by bacteriological examination of the pus. It has to be distinguished from gonorrhœal, syphilitic, and tuberculous arthritis and from joint affections due to the staphylococcus and streptococcus In the two latter conditions the general symptoms are much more severe and the local conditions are associated with more inflammatory redness of the skin. The prognosis of the condition is serious but under appropriate treatment complete recovery is possible Among the 28 cases in the literature 14 recovered, 11 died, while in three no statement is given of the ultimate results. The treatment is obviously surgical. Salicylates are useless. The evacuation of the pus by aspiration is but rarely successful and should not be relied on as valuable time may be lost. The best plan is a thorough opening of the joint, evacuation of the pus, and the removal of the fibrinous threads, which have been described as "veritable nests of diplococci." The wound should be drained for two or three days.

---

THE PREVENTION OF INFANT MORTALITY.

How best to educate mothers who by their lack of knowledge in the rearing of children help considerably to swell the infant mortality-rate is a question which is exercising the minds of all who appreciate the importance of the matter to the nation. The mayor of Huddersfield has for some time directed his attention to the subject and his efforts to educate nursing mothers in the care of their children have been already attended with not a little success. He has now in conjunction with the medical officer of health of Huddersfield issued in pamphlet form an open letter addressed to the mothers of that town in which, after referring to the successful work of the mayor of Villiers-le-Duc in France in connexion with the hygienic nursing of infants, he gives some useful recommendations for the proper care of young children. Many of these recommendations if put into practice will not only conduce to the health of the infant but also to the comfort and ease of the nursing mother herself by relieving her of much unnecessary work and anxiety. The remarks with regard to bedding are particularly worthy of consideration. It is suggested that the best cot is a basket covered with a large napkin on which is placed a thick bed of bran. The sheet should be simply placed upon the bran, the portions soiled by urine being continually removed. The suggestions with regard to food might be read with profit by most mothers and we quite agree with the recommendations with reference to fresh air. The letter concludes with an excellent practical piece of advice—

> Mothers waste a lot of time in wheeling a perambulator about, unless it is done as exercise for the mothers. The baby will get just as much good if it is put out of doors on the "*door stones*," or in a bit of garden, where there is fresh air and sunshine, just taking care to avoid direct exposure to sun and wind, it is not even necessary to have a perambulator, put the baby out of doors in a clothes basket nicely covered and sheltered and let it have full measure of fresh air. Only do not put the basket near a sink or a drain trap.

The letter is headed by the appropriate quotation—

> "Blest the babe
> Nursed in his mother's arms, who sinks to sleep
> Rocked on his mother's breast; who with his soul
> Drinks in the feelings of his mother's eye"—

And we may add blest, too, will be the mother who rears her offspring on the lines recommended in the pamphlet under notice.

THE INFLUENCE OF X RAYS IN MYELOGENOUS LEUKÆMIA.

THE influence of x rays on the nitrogenous metabolism and on the blood in cases of myelogenous leukæmia is dealt with by Dr. Owen T. Williams in the April number of the *Bio-Chemical Journal*. In order to determine the average nitrogenous excretion of a patient under treatment for this disease he was put on a diet containing 25 grammes of nitrogen per diem. The total nitrogen in the fæces and urine was determined by Kjeldhal's method and the uric acid by the Folin-Hopkin method. Blood films were examined each day and a leucocyte count was made on alternate days. In the case cited the average intake of nitrogen over a period of five days was 25·67 grammes and the average excretion of nitrogen in the urine was 11·39 gramme, the nitrogen in the fæces not being determined. The average excretion of uric acid was 0·4738 gramme per diem, a figure within the normal limits. In two other cases in the Royal Infirmary, Liverpool, a normal excretion of uric acid was recorded, contrary to the statement found in text-books that the excretion of uric acid in this disease is always increased. The patient was then treated with the x rays twice at intervals during a further period of six days, with the result that a loss in weight of one and a quarter pounds was observed, whereas prior to treatment with the x rays the weight remained constant. Each exposure lasted ten minutes, the first being given at 10 A.M. on the second day of the second series of observations. On the fourth day the patient vomited his breakfast immediately after taking it, so the treatment with the x rays was discontinued. The day before the first exposure the nitrogenous intake exceeded the output by 6 4 grammes; on the first day of exposure to the x rays this excess was reduced to 1·3 grammes and the day following to 0·45 gramme. On the fourth day the output of nitrogen in the urine and fæces exceeded the intake by 1·64 grammes and on the fifth day by 1·84 grammes. On the sixth day the nitrogenous intake again exceeded the output by 1·19 grammes, thus showing a gradual return towards the former condition before treatment with x rays. The amount of uric acid excreted in the urine gradually rose from 0·51 gramme on the first day to 0·9513 gramme on the sixth day. The number of leucocytes per cubic millimetre rose from 130,000 on the second day of the first series of observations to 250,000 on the fifth day of the second series, but fell again on the sixth day to 135,000.[1] This marked increase in the number of leucocytes, be made to improve it. He does not think that sterilised milk depôts will do much to diminish the mortality and may do much harm, "as it practically justifies the unnatural feeding of infants and helps to destroy the mother's sense of the wrong done to the infant." He says that the public conscience should be aroused as to "the crime of robbing an infant of its natural food, except under the direst necessity." Unfortunately, the poor mothers have too often a bad example set them by well-to-do mothers whose social or other engagements are considered as more pressing than the duty of suckling their offspring. A more wholesome and more motherly public opinion is wanted among women and Dr. Brown advocates the establishment in our textile manufacturing towns of maternity benevolent societies "to educate and train young mothers in the duties and responsibilities of motherhood." As he says: "The healthy breast-fed infant slept much and grew fat. The bottle-fed slept little, cried much, grew thin, and the majority died." The diet of the mothers might no doubt be more nutritious without increase of cost and the teapot might with advantage be ousted from its place on the hob. Without accurate statistics the injury, suffering, and death from fire cannot be computed but the danger from this source is a serious addition to the risks a young child has to run. It is not surprising that there are so many puny children in the streets of our towns, the wonder being that so many live to be old enough to play in the gutter.

---

SMALL-POX IN THE "THREE TOWNS."

WE have received communications concerning the occurrence of small-pox in the "Three Towns" (Plymouth, Devonport, and Stonehouse) which induce us to publish some details of the epidemic. The number of cases notified from the commencement of the outbreak in July, 1905, up to date is 214, of which a considerable proportion had been vaccinated but none had been revaccinated. In the early part of the outbreak a few cases were reported as chicken-pox which proved to be small-pox, and it is noticeable that in the Registrar-General's Report for 1904 special mention is made of the fact that this error must occasionally occur. At the suggestion of Mr. F. M. Williams, the medical officer of health of the borough and port, chicken-pox was made a notifiable disease, with the result that all the cases, for one reason or another, came before the medical officer of health. The only ones that can have escaped his notice were such modified cases as received no medical attention, and we may be pretty certain that the number has been accurately arrived at. The antivaccination spirit amongst a certain section of the public is well marked and the suggestion has been freely made, with a view to minimising the epidemic, that medical men have been notifying chicken-pox as small-pox, that being exactly the reverse of the case. The outbreak has been widely diffused, affecting the "Three Towns" in their various districts, but it has been uniformly mild in type, and with all the medical men ready and willing to assist the medical officer of health the epidemic is under complete control.

VIEW DAY AT ST. BARTHOLOMEW'S HOSPITAL.

THE traditional ceremonies of "View Day" at St. Bartholomew's Hospital will be observed this year on May 9th. A special effort is being made on this occasion to interest friends of the hospital in the work of rebuilding. The out-patient and special department block now in course of erection will be open to inspection during the afternoon and at 5 P.M. a meeting will be held in the library in aid of the funds for the projected new pathological block. In the evening at 8 30 an entertainment will be produced in the Great Hall in aid of the funds of the pathological block. It will consist of an exact reproduction of the ancient dances of the sixteenth and seventeenth centuries, with the original costumes and music of the period, and will be presented by Miss Nellie Chaplin. The entertainment has been given at various places in England but not often in London and is an artistic treat of very high order in the opinion of those who have witnessed it. Applications for tickets, price £1 1s., 10s. 6d., and 5s., should be made to the honorary secretaries, Entertainment Committee, School Offices, St. Bartholomew's Hospital, London, E.C.

PNEUMOCOCCIC ARTHRITIS IN CHILDREN.

A COMPREHENSIVE study by Dr. Hans Herzog of Heidelberg of this interesting condition with references to all the recorded cases appears in the *Jahrbuch für Kinderheilkunde und Physische Erziehung*, April 2nd, 1906. The occurrence of a purulent arthritis associated with the presence of the diplococcus of Fränkel-Weichselbaum has been recognised for some time past in this country and several papers recording cases have been published in our columns, notably one containing records of five such cases by Mr. L. S. Dudgeon and Dr. W. P. S. Branson[1] to which Dr. Herzog makes frequent commendatory references. In the present paper he records three cases which have been under his own observation and he has collected from the literature 25 others, all under the age of two years. After a careful study of these cases he finds that the condition is usually confined to one large joint, although in a few cases several joints have been affected. In the mon-arthritic group the knee-joint was involved in ten cases, the shoulder in seven, the elbow in four, and the ankle in two. In the cases where more than one joint was affected the distribution was as follows: in one case, both shoulders and the left knee; in another, both wrists and the left hip; in a third case, the left ankle and right knee; and in a fourth, the right elbow and right knee. In discussing the channel of infection Dr. Herzog points out that in 11 out of the 28 cases no evidence of antecedent pulmonary affection was forthcoming, while in eight cases of similar character in children between the ages of two and 14 years there were five cases without any antecedent pulmonary focus of the disease. On the other hand, in 55 cases of pneumococcal arthritis in adults only four occurred without pulmonary lesions. From these figures he concludes that other channels than the lung very often serve as the primary focus of the pneumococcal infection in infants and young children. The most probable primary focus is, according to Dr. Herzog, to be found in suppuration of the middle ear due to the pneumococcus. In support of this contention he quotes some observations recorded by Netter,[2] who found otitis media in 29 out of 31 necropsies on infants under the age of 30 months suffering from pneumococcal infections, with broncho-pneumonia in 12, and lobar pneumonia in one. The anatomical appearances of the affected joints are described as being in general similar to those of other suppurative varieties of arthritis, but the destructive changes are usually relatively slight and evidence of any affection of the bony structures of the joint may be difficult to discover at the time of operation although in fatal cases it can usually be made out. The capsule of the joints was distinctly thickened in the three cases observed by Dr. Herzog. A small piece of the capsule of the hip-joint in one case was examined microscopically and the capsule as a whole was found to be swollen and thickened, while the synovial membrane of the joint was infiltrated with both mononuclear and polymorphonuclear cells. A section stained by Gram's method showed a few diplococci more or less uniformly distributed through the tissues of the joint. In one case there was distinct evidence of a pneumococcic septicæmia, for the organisms tapping was employed 154 times, 385 gallons were evacuated, a quantity amounting to more than a ton and three-quarters. Lastly, in two other cases which we have mentioned three tons of serum were removed; one of these was that described by Dr. Haymaker and Dr. Graham, and the other was Paolo's case, this quantity weighing probably more than 50 times the weight of the patient. It is not improbable that some of these cases diagnosed as ascites were instances of ovarian cysts, for in several of the patients the general health seems to have suffered but little. Whatever may have been the cause of the collection of serum the very large quantities removed must have been a great drain on the health of the patient, for the loss of so much albuminous fluid must have proved very depressing. We would hardly venture to assert that the figures we have quoted have never been exceeded but 886 tappings and the removal of three tons of serum cannot often have been equalled.

INFANT MORTALITY AND BIRTH NOTIFICATION.

IT appears that the Huddersfield corporation has been successful in obtaining the sanction of a Select Committee of the House of Commons to the insertion of clauses in a local "omnibus" Bill requiring, under penalty, the future notification of each birth occurring in the borough to the medical officer of health within 48 hours of its occurrence. The objections to imposing such obligation and liability to penalty upon fathers and others in a single borough by means of clauses in a private Bill are obvious, but the result of this experiment, if the Bill becomes an Act, will possess far more than local interest. It is provided in this Bill that it shall be the duty of the father of each child born in the borough after the commencement of the proposed Act, if actually residing in the house in which the birth occurs, or in his absence of any person in attendance upon the mother at the time of the birth, or within six hours thereafter, to send or to give notice of the birth to the medical officer within 48 hours after such birth. Any person so required to give such notice failing without reasonable excuse to give or to send the same is to become liable, on summary conviction, to a fine not exceeding 20*s.*, including costs, for each offence. The corporation undertakes to pay to the person who thus notifies a birth a fee of 1*s.*, and it is further provided that the obligation to furnish this notification shall be in addition to, and not in substitution for, the existing requirements of the public and general Acts relating to the registration of birth and deaths. It is further to be enacted, in recognition that this proposed legislation is only experimental, that the clauses requiring this compulsory birth notification shall cease to be in force at the expiration of five years from the date of the passing of the Act, unless the provisions shall have been continued by public Act. While it is doubtful whether the public would be favourably disposed to the general application of these provisions proposed to be enacted in Huddersfield, or whether they will answer expectations in that borough, it would not be without interest to inquire how far the past voluntary local action of the mayor and corporation, with a view to the reduction of infant mortality, has yielded encouraging results. It appears from the official returns of the Registrar-General that the deaths of infants under one year of age during last year in Huddersfield were equal to 120 per 1000 of the births registered, showing a decline of 16 per 1000 from the proportion that prevailed in the previous year, 1904, while the mean rate of infant mortality in the 76 largest English towns in 1905 and 1904 was 140 and 160 per 1000 respectively. The annual rate of infant mortality, especially in towns, is mainly governed by the summer temperature and rainfall, which in 1905 were far more favourable than in the previous year. It may, however, be noted that the decline in the rate of infant mortality last year in Huddersfield, compared with that in 1904, was equal to 11·8 per cent., whereas the decline in the aggregate of the 76 large towns was 12·5 per cent. It is disappointing to find that the energetic and exceptional efforts made by the mayor and corporation of Huddersfield[1] in 1905 do not appear to have resulted in the reduction of infant mortality that might reasonably have been expected. With every wish for the success of the proposed experimental legislation to secure prompt birth notification in Huddersfield, it may be presumed that the probability of the enactment of similar provisions operating generally throughout England and Wales must practically depend upon clear proof of their beneficial effect in Huddersfield.

THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Sir Shirley Murphy, President of the above society, will give his presidential address at the society's rooms, 1, Upper Montague-street, Russell-square, London, W.C., on Friday, May 11th, at 5 P.M. The jubilee dinner will be held at the Hotel Cecil, under the presidency of Sir Shirley Murphy at 7.30 P.M. the same evening. Many leading sanitarians and others have accepted invitations to be present—e.g., Sir R. Douglas Powell, Bart., K.C.V.O., President of the Royal College of Physicians of London; Sir Thomas Barlow, Bart., K.C.V.O.; Sir Patrick Manson, K.C.M.G.; Sir Seymour King, K.C.I.E.; Sir Lauder Brunton; Sir Walter Foster, M.P.; Sir Francis S. Powell; Sir William H. Broadbent, Bart., K.C.V.O.; Sir Melvill Beachcroft, chairman of the Metropolitan Water Board; Sir James Crichton-Browne; Sir Michael Foster, K.C.B.; the Director-General of the Army Medical Service; Surgeon-General A. M. Branfoot, C.I.E., President of the Medical Board, India Office; Mr. J. Tweedy, President of the Royal College of Surgeons of England; the Chairman of the London County Council; Dr. Klein; and Dr. J. F. W. Tatham. It is expected that the dinner will be largely attended and members of the society are asked to apply as early as possible for tickets so that the necessary arrangements may be made. Tickets (10*s.* 6*d.* each, without wine) are to be obtained on application to Dr. Joseph Priestley, 333, Kennington-road, London, S.E., and members of the society can obtain extra tickets for any guest (or guests) whom they may desire to bring with them.

THE "INDEX MEDICUS (SECOND SERIES)."

THE "Index Medicus" was established in 1879, under the editorship of Dr. John S. Billings and Dr. Robert Fletcher and was discontinued in 1899. We wish to draw the attention of our readers to the details of the new issue of this most valuable work of reference. The present series is published by the Carnegie Institution of Washington, U.S.A., and is known as "Index Medicus, Second Series," vol. i. having been commenced in January, 1903. It is issued as early as possible after the completion of the month represented, time being allowed for the arrival of foreign journals. The editors are Dr. Robert Fletcher, and Dr. Fielding H. Garrison. This publication consists of the titles in full of books, pamphlets, theses, contributions to coöperative works and original articles in journals, transactions of medical and scientific societies, and the like, arranged under subject-headings. The titles in certain languages, as Russian, Polish, Swedish, Danish, Finnish, Hungarian, Bohemian, Roumanian, and Japanese, are translated into English. A table of contents accompanies each number and on the completion of the volume an "Annual Index of Authors and Subjects" is issued. The subject part of this annual index is elaborately subdivided, the classification closely resembling that of the occurring as it did with an increase of nitrogenous excretion and of uric acid, led Dr. Williams to conclude that the synchronous constitutional disturbance had some relation to these changes. A rise in temperature was also observed during the x ray treatment, the highest temperature recorded being 100·6°F. Dr. Williams concludes that the exposure to x rays of patients suffering from myelogenous leukæmia produces a disintegration of proteid material in the leucocytes, the products formed giving rise, in some cases at least, to grave constitutional disturbance. He suggests that when x ray therapy is being used in this disease the patient should be allowed sufficient time between each exposure to excrete the toxic products which are formed. The daily estimation of the uric acid excreted affords an indication of the length of such intervals and gives the physician a guide as to the safe dose of x rays to be used.

---

[1] THE LANCET, Dec. 9th, 1905, p. 1732.

BASIS WINES.

WE note that the Chancellor of the Exchequer proposes to bring the growing industry of the manufacture of what are called basis "wines," which are manufactured in the United Kingdom and come more or less into competition with duty paid foreign wines, under Excise supervision. The importation of grape juice for the purpose of manufacturing wine in this country avoids, as we have frequently pointed out, the spirit duties, and it is surprising that the revenue authorities have not hitherto taken action summarily in this matter, since by this device they are deprived of so much duty on wine made necessarily from material imported from abroad. Moreover, the imposition of a duty on basis wines should have an excellent moral effect, since there can be little doubt that true claret has had its character considerably damaged by the unfair competition of basis wines sold under such fraudulent titles as *Bordeaux*, *Médoc*, St. Julien, and other well-known districts in France. We trust that this fraudulent dealing will be stopped by compelling the manufacturers to use a label on the bottle honestly describing the contents. We have nothing to say against basis wines in general, and, as a matter of fact, there is no reason why a wine carefully produced from genuine grape juice in this country should not be just as wholesome as a wine produced from the same juice abroad. All we ask for is an honest description of the product.

APPENDICITIS AND PERFORATED DUODENAL ULCER.

THE coincident occurrence of two important morbid processes in a patient will always raise the question whether there be any causal nexus between them. The practical rule for diagnosis is that if any single explanation will account for all the phenomena present it is to be preferred to a suggestion of a mere coincidence. In the present issue of THE LANCET is published an account by Mr. E. G. D. Milsom of a case which was under the care of Dr. John Gutch of Ipswich. The patient was certainly suffering from an attack of appendicitis and he died from the perforation of a duodenal ulcer and the question arises, Are these two independent lesions or are they causally connected? In this case there had been hæmatemesis and this has been described by several writers as occurring as a complication of appendicitis. No case appears to have been recorded of the association of inflammation of the appendix with duodenal ulcer and that fact in itself is opposed to the idea that the two conditions are connected as cause and effect or have a common cause. On the one hand each of the conditions has a certain frequency of occurrence, and neither is very rare; therefore the chance of their occurring together sooner or later in one patient is by no means small. On the other hand, we know that appendicitis is beyond doubt the effect of a septic infection of the appendix, and also that an ulcer of the duodenum is very probably always septic in origin, though digestive action of the gastric juice may have a secondary action in actually giving rise to the ulcer. Thus there is little strange in believing that a septic infection of the alimentary canal can have given rise on the one hand to the ulceration of the duodenum and on the other to the inflammation of the appendix. It is possible that a bacterial examination of the peritoneal fluid and of the appendix might show a similarity in the form of the infection. On the whole we should be inclined to think that the two conditions were associated causally.

NITRATE OF BARIUM GIVEN IN MISTAKE FOR ARTIFICIAL CARLSBAD SALTS.

THE poisonous effects of barium salts were illustrated in a tragic manner recently in a district in Germany. By an extraordinary mistake a firm in Leipsic supplied certain of their customers with barium nitrate instead of artificial Carlsbad salts and several fatalities occurred. It is a remarkable fact that this is not the first instance in which poisonous barium salts have been accidentally supplied for artificial Carlsbad salts, so the presumption is that the crystals are identical in shape and appearance. The Carlsbad town council, which is naturally anxious to uphold the reputation of Carlsbad, declared that the indiscriminate use of the term "Carlsbad salt" to describe artificial saline mixtures is a fraud. The real Carlsbad salt is a compound obtained from the evaporation of the water of the Carlsbad springs and is exported under the control of the Carlsbad authorities, so that such accidents are said to be impossible when the real Carlsbad salt is prescribed.

RECORDS IN PARACENTESIS ABDOMINIS.

IN THE LANCET of April 21st (p. 1108), we printed an account by Mr. F. H. Maberly of a patient under his care, who suffered from marked ascites and who was tapped altogether 69 times and at each tapping about two gallons of serous fluid were removed, or about 140 gallons in all. The case is remarkable both for the number of times the patient was tapped and for the total quantity of fluid removed, but a search through medical literature will show several which surpass Mr. Maberly's case, both in the number of tappings and in the total quantity removed. Dr. D. Dickinson, of the United States Navy, reported a case of a man, 28 years old, who was tapped 69 times within 17 months. Dr. Farrar recorded a case in 1885 where he tapped the abdomen 78 times for ascites. Dr. Haymaker and Dr. Graham in 1872 described a case under their care in which the abdomen was tapped 130 times within 18 years and an instance was reported in the *Bulletin des Sciences Médicale*, in which there were 154 tappings. Paolo related a case in which the patient was tapped 255 times within ten years. A case was reported in Paris in which the abdomen was tapped 300 times, but the climax is reached in the case of a woman reported by Cann to the Paris Academy of Medicine on whom paracentesis abdominis was performed no less than 886 times within 15 years, or about once a week for the whole time. When we come to consider the total quantity of fluid removed in such cases as these the amounts seem enormous. In Mr. Maberly's case the total amount appears to have been about 140 gallons, or 1400 pounds, if we take the specific gravity of the fluid as equal to that of water, but it is really a little greater. Now 1400 pounds are some 200 pounds more than half a ton. In Dr. Dickinson's case, mentioned above, the total quantity was rather less. In Dr. Farrar's case 234 gallons were drawn off and this exceeds a ton by 100 pounds. Dr. W. E. Hyde in 65 tappings removed over one and a half tons of serum, or 371 gallons, and in the case already mentioned where populations. From a table in the present report we gather that whilst among males at all ages the death-rate in the urban group exceeded that of the rural by about 5 per 1000, among females the urban excess was less than 4 per 1000. If the English counties be taken separately far greater differences of mortality will be observed. Thus among persons of both sexes in Westmorland and Oxfordshire the rate was only 11½ per 1000 of the population, whilst in Lancashire it was 20½, a difference of no less than 9 per 1000.

A most valuable portion of the report is that which forms the subject of Dr. Tatham's letter to the Registrar-General and which, inasmuch as it discusses the various causes responsible for English mortality, possesses more than ordinary interest for students and practitioners of medicine. Dr. Tatham prefaces his analysis of the causes of death by referring to the subject of disease registration, the necessity for which as a national institution has been insisted on by the Interdepartmental Committee on Physical Deterioration and the practicability of which has been affirmed by the medical officer of health of the county of London in his report for 1904. It is deplorable that the United Kingdom, which alone among the nations possesses a complete organisation for the medical treatment of the poor, and every important town of which is replete with hospital provision for the sick, should allow the accumulated records of sickness to run to waste solely because of the apathy of the authorities who are intrusted with the preservation of the public health. We hope that the suggestion now once more put forth will be adopted, and that at any rate the beginning of a system of sickness registration will be set on foot by the authorities of the London hospitals who might furnish for publication to a central bureau periodical returns of the sick cases coming under their care. We are convinced that such returns would be of great value and if an example were set by the great metropolitan institutions it would eventually be followed in all the important towns in the country. The systems of sickness registration and death registration are complementary the one to the other, and it is plain that neither of them by itself can be regarded as satisfactorily fulfilling the requirements of vital statistics. That much may be done in the direction of a national registration of sickness has already been proved by the Local Government Board—not in respect of diseases generally but in respect of those infectious diseases the notification of which to sanitary authorities is compulsory under statutory provision. Although their returns are at present marked confidential, and therefore are not available for general use, it may be mentioned that the Local Government Board now issues periodical records of the cases of infectious disease notified throughout England and Wales, so far as these can be ascertained in time for inclusion in the Board's weekly bulletin. The cost of the medical treatment of the sick whether by Poor-law institutions or by public hospitals is eventually borne by the ratepayers, and it is to be regretted that the valuable information which present circumstances might readily afford is not as yet available either for curative or for preventive purposes.

Respecting the fatality of the common infectious maladies the full particulars for 1904 provide suggestive information. Small-pox has been present during the year in less than the usual severity, but in parts of the North of England it has threatened at times to assume epidemic proportions, the mortality ranging from a rate of 16 per 1,000,000 in Lancashire to 66 per 1,000,000 in Northumberland. No estimate is offered as to the number of cases of small-pox that have occurred—we presume because of the incompleteness of the returns under the Notification Act—but it appears that in the year under notice 507 deaths were definitely referred to small pox and, what is of no less importance, that 104 other deaths were indefinitely referred to chicken-pox, most of the latter being probably unrecognised cases of the graver disease.

The mortality from diphtheria in England and Wales has steadily fallen, the present rate being little more than half of what it was five years ago. In addition to the deaths definitely returned as from diphtheria the registers contain entries of a considerable number of deaths indefinitely referred to "croup," neither "spasmodic" nor "membranous." In order, however, to obtain an approximate statement of the mortality caused by diphtheria the deaths from that disease and those from so-called "croup" are classed together. The fall in London mortality from diphtheria is especially noteworthy, for whereas in the five years ended 1900 diphtheria was fatal in the average proportion of 478 per 1,000,000 of the population at all ages, in the year 1904 the rate did not exceed 156 per 1,000,000, being considerably below the average for England and Wales. In the year 1904 the counties of Durham, Stafford, and Nottingham, together with certain of the Welsh counties, suffered most severely from diphtheria. In the first-named county the rate, which had risen rapidly throughout the five preceding years, further rose in 1904 to 285 per 1,000,000. In Wales the county of Glamorgan, with parts of Monmouth, still constitutes an area of undue mortality from this disease, the rate ranging from 202 per 1,000,000 in Cardiff to 877 per 1,000,000 in Portardawe. Staffordshire still experiences a mortality from diphtheria considerably in excess of the English rate, although since 1900, in which year the rate amounted to 526 per 1,000,000, the mortality has fallen steadily. In Nottinghamshire the diphtheria mortality has risen continuously from a rate of 131 per 1,000,000 in the year 1899 to 235 per 1,000,000 in 1904.

The eminently preventable disease, enteric fever, still continues to show less fatality in England and Wales as years go on, the disease having accounted for the lowest death-rate on record in the year under notice. Enteric fever attains its highest fatality somewhere between the ages of 15 and 35 years. At all ages except those from five to 15 years it is most fatal to the male sex. The disease is far more destructive to life in the urban than in the rural group of counties; this is especially noticeable as regards males dwelling in towns who die from it practically twice as fast as do those dwelling in country districts. Among counties containing more than 100,000 inhabitants Durham, Lancashire, the East and West Ridings of Yorkshire, and Nottinghamshire were most severely visited in the year 1904 the rates of mortality from this disease ranging from 137 per 1,000,000 living in the first-named county to 162 per 1,000,000 in the county last named. In consequence of the reported presence of cerebro-spinal fever in several parts of England special inquiries have been made as to the actual nature of the malady in cases where deaths have been certified as from cerebro spinal meningitis without further qualification. It is therefore reassuring to learn that in the last five years the deaths from "cerebro-spinal fever" have averaged not more than 55 annually. It is satisfactory to note that in the last four years only two deaths have occurred in England and Wales from hydrophobia, both of which were registered in 1902. This happy immunity from an exceptionally terrible disease is due to the proper administration of the law as regards the muzzling of dogs. In the decennium ended 1890 the deaths from hydrophobia averaged 29 yearly.

Pneumonia is one of the diseases that have shown no tendency to decline in recent years. It is probable, however, that some of the deaths which in earlier years would have been attributed to capillary bronchitis are now returned as from broncho-pneumonia, so that the increase which was recorded in 1904 may be in part apparent only. In this connexion it may be well to intimate that wherever capillary bronchitis is regarded as synonymous with broncho-pneumonia the use in medical certificates of the latter term in preference to the former will tend to increased accuracy in the records of both forms of respiratory disease.

With reference to our leading article upon this report, which appeared in our issue of April 21st, we have received a letter from a correspondent, who is, by the way, an authority on vital statistics, in which he offers a correction of a passage we quoted almost verbatim from the report itself. In this passage we refer to the difficulty of accounting for disparities in the birth-rates of the several European countries, a difficulty which would probably disappear if allowance could be made for differences in the age and sex composition of the population, especially with respect to the proportion of women of conceptive ages. Our correspondent draws attention to a fact, which we confess had escaped our notice, that in the current number of the journal of the Royal Statistical Society there appears a paper by Dr. A. Newsholme and Dr. Stevenson of Brighton in which factors are presented for correction of birth-rates for variations of age and sex distribution, so that any person may readily ascertain how much of the differences of birth-rate is due to the statistical causes alluded to in the report and how much to real differences of fertility. We gladly give publicity to this reference but in so doing we would

Index Catalogue of the library of the *Surgeon-General's* Office, United States Army. The index of the volume for 1903 occupies 187 pages in double and triple columns. The subscription price (to be paid in advance) is $5 per annum in the United States and Canada; in foreign countries, 25*s.* or marks, 30 francs or lire. Communications relating to subscriptions should be addressed: Carnegie Institution, Washington, District of Columbia, U.S.A. Communications in relation to the bibliography should be sent to: Editors Index Medicus, Washington, District of Columbia, U.S.A.

THE STATUS OF THE HAMPSTEAD GENERAL HOSPITAL.

IN our issue of April 14th we mentioned that at a meeting of the Hampstead division of the British Medical Association it was decided to call a conference of the whole of the medical practitioners in the neighbourhood upon the management of the Hampstead General Hospital. It has been decided that this conference shall be held on Saturday, May 5th, at 4 30 P.M., in the concert hall of the Hampstead Conservatoire. The agenda of the conference are to consider the resolutions passed at the meeting of the local division of the British Medical Association referred to above and to consider the circular letter and question which have recently been issued by the council of the hospital to the medical profession in Hampstead. As we have said upon a previous occasion, the matter is entirely one for the local profession to decide and we see no reason why a satisfactory solution of the problem should not be arrived at, as both the authorities of the hospital and the members of the medical profession in Hampstead itself and the surrounding district seem anxious for a settlement of the question.

AS was mentioned in THE LANCET of April 28th, Baron Takaki, F.R.C.S., will deliver a series of lectures at St. Thomas's Hospital, on May 7th, 9th, and 11th, upon the Preservation of Health among the *Personnel* of the Japanese Army and Navy. The lectures will be founded on the experiences of the late Russo-Japanese war, but Baron Takaki wishes to state that it is incorrect to describe these experiences as personal. Our distinguished *confrère* retired from active service in the Japanese navy more than a dozen years ago but he visited Manchuria during the war as a spectator.

THE annual meeting of the Invalid Children's Aid Association will be held on May 30th, at 3 P.M., at 17, Bruton-street, London, W., by kind permission of Lord and Lady Stratheden and Campbell. Sir Frederick Treves will preside and the Bishop of London and Mrs. Craigie (John Oliver Hobbes) will be among the speakers. Admission by application to the Secretary at 69, Denison House, Vauxhall-bridge-road, London, S.W.

H.R.H. the Princess Royal will lay the foundation-stone of the new buildings of the Bolingbroke Hospital, Wandsworth Common, London, S.W., to-day (Saturday, May 5th). Admission will be granted to those holding tickets for reserved seats by the "West Entrance," Wakehurst-road, but cannot be obtained before 2 P.M. or after 3 P.M. The secretary to the building committee is Mr. J. C. Buchanan.

THE ninth annual meeting of the Childhood Society will be held at 7, St. James's square, London, S.W., on Tuesday, May 8th, at 3 P.M., when an address will be delivered by Sir Edward Brabrook, C.B., F.S.A.

THE half-yearly dinner of the Glasgow University Club, London, will be given in the Trocadéro Restaurant, Piccadilly-circus, W., on Friday, May 25th, at 7.15 for 7.30 P.M., when Sir Thomas McCall Anderson, Regius professor of medicine in the University of Glasgow, will occupy the chair. Applications for dinner tickets should be made to the honorary secretaries, 63, Harley-street, London, W.

THE whole of the medical profession will share our deep sympathy with Professor Augustus D. Waller, F.R.S., director of the Physiological Laboratory in the University of London, who has lost his daughter, a child of 12, in the recent shipping disaster off Sark. Professor Waller's son, who was also on board, was saved but the companion of the two children, Miss Smith, was drowned.

THE summer session of lectures on diseases of children at Great Ormond-street Hospital for Sick Children will be opened by Mr. W. Arbuthnot Lane, who will lecture on Cleft Palate on Thursday, May 10th, at 4 P.M. The lectures are given every Thursday at 4 P.M.

WE heartily congratulate Dr. Alfred Ernest Jones upon his complete exoneration from the infamous, and perfectly incredible, charges brought against him in connexion with his official visits at the schools for defective children.

SIXTY-SEVENTH ANNUAL REPORT (FOR 1904) OF THE REGISTRAR-GENERAL.

I.

IN THE LANCET of April 21st, p. 1120, we reviewed in a general manner in a leading article the first part of the Registrar-General's report on the births, marriages, and deaths recorded in 1904. We now proceed to notice in detail that section of the report which treats of the causes and geographical distribution of mortality. Sir William Dunbar still continues his useful comparison of English vital statistics with those of our British Colonies and dependencies as well as with those of foreign countries, thus considerably augmenting the scope and importance of his work. The particulars of this comparison will be found *in extenso* at page 30 of the report; we may have occasion later to refer to the wide lessons to be drawn from these figures but for the present we will deal with the mortality statistics during 1904 of England and Wales.

English mortality from all causes in 1904 was at the rate of 16·2 per 1000 of the population and was therefore higher by nearly 1 per 1000 than the rate of the preceding year, which had been the lowest on record. Nevertheless the rate for 1904 still compares favourably with the quinquennial average and the excess over the rate of the previous year may readily be accounted for by variations in the weather conditions of the two periods. Although of the 500,000 deaths recorded in 1904 less than 2 per cent. were registered as uncertified either by medical men or by coroners, we learn that more than 9 per cent. of the total were referred to causes so indefinite as to be worthless for purposes of classification. We further learn with regret that in the 6½ per cent. of the deaths which are made the subject of inquests the certificate of the coroner in many cases leaves it uncertain whether or not medical evidence of cause of death had been given in his court. The death-rate here quoted as 16·2 per 1000 is, of course, the average rate for England and Wales, without distinction of sex, age, or locality. Taking one year with another the mortality of males is higher than that of females by about 14 per cent. and it is notorious that the rate varies enormously at the several stages of life. Again, the fatality of most diseases is known to vary considerably according as a given area contains a large or a small proportion of urban inhabitants. For this reason, in each annual report issued since 1900 statistics have been given showing the mortality in two groups of English counties, the one being urban in character and containing a total population of 18,000,000, the other rural with a population of 4,333,000; the rates in these areas are then made comparable by correction for age and sex differences of the

the universities *ought not* to be thus trammelled and hidebound. Freedom for each Scottish University to develop along the lines most suited for its particular circumstances is surely the best for each. The business committee rightly asks, Why should Parliament not be asked forthwith to grant to each university autonomy in some measure corresponding to that conferred on the younger universities in England? The recommendation that the University Court should take this matter up at once will commend itself to all who realise the necessity of enabling the Scottish Universities to adapt themselves readily to the changed conditions of the present times and to the wider conception of the functions of the highest educational institutions in the country which is now widely entertained.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

A Comitia was held on April 26th, Sir R. Douglas Powell, Bart., K.C.V.O., the President, being in the chair.

The following gentlemen, having passed the required examination, were admitted as Members of the College: Frederick Samuel Langmead, M.D. Lond., L.R.C.P. Lond.; Charles Hewitt Miller, M.A., M.D. Cantab., L.R.C.P. Lond.; and Athelstane Iliff Simey, B.A., M.D. Cantab., L.R.C.P. Lond.

Licences to practise physic were granted to 101 gentlemen who had passed the necessary examinations.

A report was received, dated April 5th, from the examiners for the Murchison scholarship, awarding the same to Henry Francis Bell Walker, a student of Guy's Hospital. Mr. Walker was in attendance and was handed the award by the President.

The following Members were, on the nomination of the council, elected Fellows of the College: Dr. Samuel Walton Wheaton, Dr. Frederick William Burton-Fanning, Dr. John Hill Abram, Dr. George Henkell Drummond Robinson, Dr. Richard Tanner Hewlett, Dr. Ernest Graham Gordon Little, Dr. Charles Richard Box, Dr. Maurice Craig, Dr. James Purves Stewart, Dr Thomas Jeeves Horder, Dr. James Hugh Thursfield, and Dr. Edward Farquhar Buzzard.

The following communications were received: 1. From the honorary secretaries of the Second International Congress on School Hygiene, to be held in London, August 5th to 10th, 1907, inviting the College to appoint two representatives to be members of the general committee. It was resolved that representatives of the College should be appointed and it was left to the President to nominate them. 2. From the University of Aberdeen inviting the College to send a delegate to represent the College at the Quatercentenary Commemoration Festival in September next, to be the guest of the University and of the city. The invitation was accepted and it was resolved that the President should represent the College on that occasion. 3. From Messrs. Goupil's (art publishers) successors, asking permission to photograph the portraits of Dr. Arbuthnot and of Sir Samuel Garth, in possession of the College, for illustrating a work which they have in hand. The request was granted. 4. From the secretary of the Royal College of Surgeons of England reporting proceedings of its Council on April 5th.

The quarterly report, dated April 6th, of the College Finance Committee was received and *adopted*.

A communication was received from Dr. J. Abercrombie, resigning the office of curator of the museum. The resignation was accepted and the thanks of the College were ordered to be given to Dr. Abercrombie for the services he had rendered to the College. Dr. W. H. Allchin was appointed to the office on the nomination of the President.

The books and other publications presented to the library during the past quarter were received and the thanks of the College were ordered to be returned to the donors.

The quarterly report of the Examiners for the Licence on the January examinations was received and adopted.

The President then dissolved the Comitia.

At the meeting of the Chard (Somerset) rural district council held on April 22nd it was resolved to erect a small-pox hospital at a cost of about £250.

THE

FIFTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

Held at Lisbon, April 19th—April 26th, 1906.

FINAL MEETING OF THE GENERAL INTERNATIONAL COMMITTEE.

(From our Special Commissioner.)

Lisbon, April 27th.

On Thursday morning, April 26th, at about 10 o'clock, the International Committee met in the great hall of the new School of Medicine and first decided by 38 votes against 23 that the Government delegates might be represented by substitutes. This was fortunate, for the *Ophir* was by that time far away at sea on its way homewards with Sir Dyce Duckworth on board. Sir John Tyler, however, was by this vote accepted as his substitute. Then came the question of where the next International Congress should meet. The General Secretary, Dr. Bombarda, explained that four positive invitations had been received. These were from Athens, Brussels, Budapest, and New York; some advances of a less positive character had also been made from Tokio. The executive committee of the present Congress had been in negotiation with the Hungarian committee for several months and found that the Hungarians were evidently animated by the best intentions and that the Royal Government and the municipality of Budapest had already voted funds in order that the Congress should be properly organised. The American delegates nevertheless made a great struggle for New York. Remembering, however, that the International Congress on Tuberculosis accepted the invitation to meet in the United States of America before the next Presidential election, the two Congresses would undoubtedly clash. It is not practical to expect European medical men to go to America twice within the course of a few months. Ultimately Budapest was accepted by 38 votes against 26 and one abstention. The next Congress will, as usual, be held in three years, but a request will be made that the invitations sent for the *ensuing* Congress shall not bear a date, so that when at Budapest the Congress will be free to decide whether it will meet again after an interval of more that three years.

A petition, which was signed by several medical men dentists, was then read, asking that dentists who were not medical men should be admitted to the Congress. Dr. Cruet (France), on the contrary, congratulated the committee for having excluded the dentists who were not medical men and when the matter was put to the vote a large number of hands was held up in favour of excluding dentists who are not fully qualified practitioners. The contrary opinion was not clearly taken but it was quite evident that the decision was approved by an overwhelming majority.

The fact that the General International Committee had at a previous sitting decided to allot the Paris prize to Dr. Ehrlich and the Moscow prize to Dr. Laveran was mentioned, and then Dr. Bombarda hurriedly read out some of the resolutions adopted by the sections. It was difficult to understand why this was done as there was no opportunity of discussing the points raised or voting upon them. Such votes or semblance of votes as were given at this stage were recorded very carelessly. Many persons were in the room who did not belong to the Committee and there was nothing to prevent them voting also.

The Closing Ceremony.

A little after 2 P.M. the great hall was well filled with members of the Congress who came to assist at the solemn *closure*.

The chair was occupied by the President of the Congress, Councillor Dr. Costa Alemão, with the general secretary, Dr. Miguel Bombarda, by his side. Both wore the broad lilac ribbon, gold chain, and crimson cross of the Grand Cross of the Order of Santhiago, which had just been conferred on them by the King in recognition of their distinguished scientific services.

The President read out a statement in which he said that all had gone well. From abroad and at home willing help had been received and then the President proceeded to thank everybody. On mentioning Dr. Bombarda's name a great ovation took place, everyone rose, shouted, waved hats, handkerchiefs and press notebooks. The treasurer, Dr. Alfredo remark with regard to the correction of rates of birth (as distinguished from rates of death) that it is questionable policy to pretend to a degree of accuracy which must obviously be unattainable until the statutory registration of stillbirths becomes an accomplished fact in England, as, we believe, it has long been in several foreign countries.

(To be continued.)

UNIVERSITY OF EDINBURGH: IMPORTANT PROPOSED ALTERATIONS IN THE MEDICAL CURRICULUM.

SOME time ago an epitome of a draft ordinance prepared by the court of the University of Edinburgh bearing upon alterations proposed to be made in the regulations for degrees in medicine was given in THE LANCET. There has just been circulated to the members of the general council of the University a more detailed account of the proposed alterations, along with the comments upon them by the business committee of the council. These are so very important that it is desirable to mention them in considerable detail. The proposed alterations are the outcome of numerous conferences and have been discussed by the court, the Senatus, and the Faculty of Medicine. The draft ordinance referred to only deals with the alterations in so far as they require the sanction of the King in Council before being given effect to. The comments and suggestions of the business committee of the council are arranged under the different clauses of the draft ordinance.

Under *Clause I.* it is indicated that the general idea of the scheme is that students should be allowed more freely to pass their examinations by instalments, so that when they have received their instruction in a particular subject they may be forthwith examined in it, and be thus enabled to concentrate attention upon the subjects in which they are immediately undergoing tuition without being distracted by examination requirements in subjects previously studied.

By *Clause II.* it is intended that students may appear at once for examination in any one or more subjects of the *first* division after having attended the class or classes; the *first* division includes botany, zoology, physics, and chemistry.

Clause III. provides for physiology being passed whenever the qualifying course therein has been taken. The examination in anatomy may be taken at any time after the end of the first half-session of the third winter. It is assumed that the recognition of a "half-session" concedes by implication one of the demands supported by the general council for a system of three examinations a year.

Under *Clause IV.* students who have begun medicine in May are to be examinable in pathology at the end of the fourth summer session, and the materia medica examination is to come at the end of the fourth winter. A very important proviso is, however, introduced to enable candidates to be examined in practical pharmacy, and also in the physical, chemical, and botanical characters of medicinal substances at any time after attendance on the qualifying course therein. This the committee thinks indicates that elementary parts of the subject are to be relegated to an earlier stage in the curriculum, while therapeutics is to be reserved until the students have some acquaintance with clinical work.

By *Clause V.* the subjects of the fourth or final examination may be taken after the previous examinations have been passed as follows: forensic medicine and public health at any time; midwifery after the first half session of the fifth winter; medicine and surgery at the end of the fifth winter; and clinical medicine and surgery and gynæcology at the end of the fifth year. The draft ordinance does not prescribe the sequence in which classes are to be attended, but it is thought that its provisions will afford a stimulus to students to follow out the logical order. Two matters not dealt with in the draft ordinance the committee has considered. One of these is that when examinations may be taken in single subjects immediately upon the conclusion of a course of instruction therein the record of work done by the candidate in the class which he has attended ought to form a factor in determining whether he is qualified. The other is that in the opinion of the committee the Senatus should be intrusted with power to restrain a student when desirable from entering upon new subjects of study before he has cleared the examinations in the prior subjects. To enact an absolute bar to such further study might be unwise but to confer on the Senatus a full discretion would be eminently useful, would be a kindness to the student himself, and make for his ultimate efficiency as a practitioner. The alterations embodied in the draft ordinance and the additions recommended by the business committee of the general council reveal an enlightenment of opinion which will be generally and widely appreciated by alumni of Edinburgh. The practical concession of the division of the *annus medicus* into three terms instead of two and of having examinations corresponding to them would be a great boon to the student and whatever lightens the student facilitates and benefits the teaching. Liberty to pass the examination in physiology and anatomy at an earlier date than has hitherto been possible ought to be greatly to the student's advantage in allowing him to give more undivided attention to pathology, therapeutics, and the subjects of the final examination. The separation of pharmacy and the more physical aspects of materia medica from therapeutics is also a step in the right direction; in fact, therapeutics ought properly to be definitely included in the final subjects. The recommendation of the business committee that the Senatus should have power to prevent a student attending classes on more advanced subjects when he has not passed the earlier subjects will meet with the approval of those who have had experience of students as their teachers and examiners. To some it will be a surprise to know that the Senatus has not hitherto had this power. The want of it has allowed students to attend not only systematic but practical courses of instruction when they were not in a position to benefit by the instruction and in a practical class this always means that they act as a drag upon the class and materially complicate and hinder the teaching.

The Carnegie trust.—The new regulations issued by the executive committee of this trust in the fifth annual report have been already given in detail in THE LANCET. The business committee of the general council, in referring to the changes, pertinently points out that by the new regulations the attendance of ordinary students at optional and supplementary classes will be cut down or at least deferred. As these extra classes have often been the direct or indirect result of the other part of Mr. Carnegie's endowment, that for the increase of teaching power, the position is getting anomalous and will demand early attention. One way out of the difficulty would be for the universities to charge annual composition fees for instruction and not fees for individual classes, leaving for adjustment the classes ordinary or extra which a student should be entitled to attend according to the circumstances of his academic career at the time and his own proved fitness.

Greater liberty for the Universities.—It is not generally known that the Scottish universities are strangely hindered in their evolution by Act of Parliament. The court of each university has power to make such ordinances as it may think fit, with the approval of the Sovereign in Council. Before, however, submitting any such to the Privy Council for approval each new ordinance must be communicated in draft by the court to the Senatus and to the general council for their opinions. After final adjustment by the court it has then to be communicated to the courts of the other Scottish universities. Any of the other universities or any person directly affected by the new ordinance may within one month notify dissent and within another month lodge a representation with the Privy Council. The ordinance may be referred to the universities committee of the Privy Council for a report to the Sovereign but cannot be approved until it has been laid before both Houses of Parliament during 12 weeks of session to give those Houses an opportunity of presenting an address praying the Sovereign to withhold assent. The business committee of the general council aptly terms this procedure slow and cumbrous and experience has shown that it is far from encouraging in its results. It is, moreover, in striking contrast with the autonomy enjoyed by the lately created English universities. By this procedure any of the Scottish Universities can practically block any important change which the University of Edinburgh may desire to make and instances are given illustrating how undesirable this state of affairs is. There is no doubt that with it was useful for insertion into infected cavities or as a dressing for infected wounds.

MEDICINE.

Dr. G. W. M'Caskey (Fort Wayne, U S A.) read a paper on

The Action of Diseases of the Digestive Tract in the Production of Arterial Hypertension.

The splanchnic circulation was regarded as one of the most important regulatory mechanisms of the arterial tension and was closely connected with the digestive organs. Diseases of the digestive organs might affect the tension in two ways: (1) by reflex nerve influences, and (2) by the absorption of toxic products. The latter was probably the more important method. Three questions were then discussed: (1) Could chemical products in the circulation lead to prolonged hypertension and arterial sclerosis? (2) Did such products act directly or indirectly? and (3) Could the products of the intestinal flora lead to such results? Dr. M'Caskey related clinical evidence in support of his conviction that toxic absorption from the intestines led to arterial hypertension.

Dr. Juliano Moreira and Dr. Afranio Peixoto (Rio de Janeiro) communicated a report on

Mental Diseases in Tropical Climates.

They summed up their observations under the following headings: 1. No pathological form of mental disease differing from that of other climates existed in the so-called tropical zones, neither amongst the natives of the country nor among the Europeans. 2. There was no relationship between the cases of insanity occurring in Rio and the other towns of Brazil and the maximum temperature of these towns. 3. There was no correlation between the climatic states (temperature, moisture, &c) and the number of cases of insanity in the warm parts of Brazil 4. The meteorologic and seasonal influences on the insane presented individual differences in warm climates just as they did in cold climates and no general rules on that connexion could be formulated 5 The influence of the tropics on the nervous system of persons coming from cold climates varied with the individual but was usually associated with their modes of life and their nervous organisations. 6 There was no reason to believe that in tropical climates there was a greater frequency of psychoses connected with malaria. Their presence in malarial patients depended on other factors. 7 The climate had no influence on the symptoms of the various psychoses. The cause of any differences depended on the degree of education of the individual. A pure descendent of pure Caucasians if brought up in the interior with ignorant people would exhibit the same elementary insanity as the uneducated coloured people.

Dr. Francisco Fajardo (Rio de Janeiro) read an official report on

The Etiology and Prophylaxis of Yellow Fever

In 1900 the American Commission had published its experiences, which had given a new direction to the study of yellow fever by demonstrating its transmission by the *stegomyia calopus.* The history of the triumph of Cuba over yellow fever was described; it had been accomplished by the careful methods of exterminating the mosquito adopted by Dr. Gorgas. Dr. Fajardo believed that in time there would be no cases of yellow fever in Rio de Janeiro, New Orleans, or in the zone of the Panama Canal. He summed up his conclusions thus: 1. Although Sanarelli's works had not received scientific sanction with regard to the cause of yellow fever they were a remarkable scientific contribution inasmuch as they shed great light on the pathological anatomy of the disease. 2. Up to the present insignificant benefits had arisen from the recent study of yellow fever with regard to its diagnosis, prognosis, and treatment. 3. The etiology of yellow fever had not so far been discovered definitely but recent research had been of value in pointing out the direction for future work; this had been done by the American commission and the Pasteur mission. 4. In Brazil the obstinate and prolonged struggle against the mosquito in general and against the propagation of yellow fever in particular would soon banish the disease from Brazilian territory, as was witnessed by the work effected in connexion with the discovery of the epidemic sources in Rio. 5. Simple transmission of yellow fever by the stegomyia could occur during the day between 9 and 3 o'clock, though rarely. 6. To-day the prophylaxis of yellow fever rested on scientific facts and could be applied everywhere with a satisfactory result.

Dr. Aarao Ferreira de Lacerda (Oporto) read a paper entitled—

Some Observations on the Intensive Mercurial Treatment of General Paralysis.

From February, 1904, to March, 1905, he had, in conjunction with Dr. Magalhães Lemos, experimented therapeutically in 15 cases of general paralysis, in accordance with the precepts set forth by Leredde in his book, "The Syphilitic Nature and the Curability of Tabes and General Paralysis." In 11 out of the 15 cases syphilis had undoubtedly been in operation, in one alcoholism only was present, in one the history was uncertain but syphilis was probable, and in two no history could be ascertained. All were marked cases of general paralysis, having passed through the early stage of the disease. The time elapsing between the syphilitic infection and the onset of general paralysis had in 13 of the cases varied from five to eight years; in two cases it had been over ten years. The following treatment had been administered: (*a*) First mercurial treatment from Feb. 14th to May 13th, 1904, with an interval of rest from March 28th to April 6th. Intramuscular injections of benzoate of mercury every second day and later daily in doses of four and a half, increased to 11, milligrammes. Then followed a month of rest (*b*) Second mercurial course from June 13th to July 6th; injections of hermophenyl daily, rising from one centigramme to 12 centigrammes dose. After an interval of ten days' rest iodide of potassium was given after three meals daily, the dose being increased from one gramme to 12 grammes daily. After an interval of 33 days the second course of iodide of potassium was commenced. A daily dose of three grammes was gradually increased to 12 grammes. An interval of 65 days was then allowed. (*c*) The third course of mercurial treatment was started on Jan. 27th and lasted to March 3rd, 1905. Intramuscular injections of hermophenyl were given, at first every second day and then daily, in doses increasing from one to 12 centigrammes Detailed accounts were given of the symptoms of the 15 cases and the results of treatment were not encouraging. Treatment by mercury had always been stopped if the patient lost weight or developed albuminuria or an oscillating temperature. The conclusions arrived at were 1. That mercury can be administered in the quantities indicated without danger of skin manifestations, stomatitis, or intestinal disturbance. 2. In each course of treatment not more than 22 injections should be made and they must be injected deeply into the upper third of the buttock. 3. Mercury was injurious in the third stage of general paralysis and (4) in the second stage it was harmless; the disease followed its usual course independently. 5 Iodide of potassium in all cases led to tachycardia and feeble pulse. 6. The biniodide of mercury was an excellent preparation for this method of treatment. The hermophenyl produced no pain and was easily managed. 7. The lack of success in the cases described was explicable because none of them had been treated in the initial stage of the disease.

Dr Antonio Muñoz Ruiz de Pasanis (Cazorla) read a paper on

Cardiac Arrhythmia.

He said that arrhythmia might be either organic or functional, the former being due to causes which affected the structure of the cardiac muscle and the latter being brought about through the agency of the nervous system. There were, however, some disturbances of the innervation of the heart which did not give rise to arrhythmia. Any interference with the pneumogastric or the great sympathetic would, for instance, produce not arrhythmia but tachycardia or bradycardia. It was not at present possible to classify the various forms of nervous arrhythmia in accordance either with clinical observation or physiological experiment. The mechanism of arrhythmia could be explained in conformity with the distribution of the muscular fibres in the auricles and ventricles, and their mode of action. The muscular fibre of the heart always contracted rhythmically, rhythmic action being one of its essential properties, but rhythmic action did not imply the co-existence of synchronism, because two organs might move rhythmically although not synchronously. For two organs to move synchronously there must be some link connecting them, and there must also be a cause which determines the instant when the movement begins. Now the auricles and

Lopes, the assistant secretaries, Dr. Antonio de Azevedo, Dr. F. de Mattos Chaves, Dr. Mello Breyner, Dr. Silva Carvalho, and Dr. Azevedo Neves, were also mentioned and their names greeted with well-merited applause. Nor was the press omitted, and gratitude was expressed for its services in having helped to draw people to the Congress and for diffusing the knowledge which the Congress had attempted to bring forth. Of course, the King and all those who had provided any sort of hospitality were mentioned in grateful terms and the speech concluded with cheers for the Royal Family, for Portugal, and Hungary as the host of the next congress.

Dr. FERDINAND CARO, who was the general secretary of the last Congress which met at Madrid, now rose on behalf of all the foreign delegates and members to thank the King of Portugal who came in person to the Congress so as to show his courtesy and his esteem of the medical profession. The members had attended so as to describe the progress accomplished in each country. Some came to teach, others to learn, and all to coöperate in the advancement of science. In the book of science they had now written another page. The work was over; in a few hours many would be leaving Portugal, but they would never forget what they had seen and the kindness they had experienced.

The SECRETARY-GENERAL then announced to whom the Moscow and Paris prizes had been given and the Congress applauded the choice made. Then the band, placed in a neighbouring room, persisted in playing a somewhat melancholy hymn which presumably is the official Hungarian National Anthem. The Rackotsky march would certainly have been more generally recognised and appreciated. The bandmaster, however, seemed to think it his duty to play the official hymn every time he heard the word Budapest mentioned. The Congress thereupon stood meekly like so many penitents in gloomy silence till the band had finished its lugubrious performance and the business of the day could be resumed. It was only at the cost of hearing the hymn over and over again that we could be informed who would preside at Budapest. The Sixteenth International Congress of Medicine, which is to meet in 1909, will have for President *Professor Colman Müller and for general secretary Professor* Emil Grósz.

Dr. DE TOTH, on behalf of Hungary, returned thanks to the Congress for having accepted the invitation tendered by his fellow countrymen. He appealed for help from all nations and promised that the Hungarians would do their best to insure the success of the next Congress.

The Secretary-General had contrived during the course of this sitting to again read out very hurriedly some of the resolutions carried in the sections. This was a mere form and no serious vote could be taken. In fact, the marvel of it is that, in spite of the repeated hymn-playing, the whole sitting lasted barely more than half an hour. The wearying succession of nationality speeches had been replaced by a few very brief but eloquent sentences from Dr. Caro. With the exception of the President's opening address there had been no speeches; thus to the surprise of all and the relief of not a few the sitting was concluded in less time than at any of the previous International Congresses. Formal notice of termination was followed by an outburst of tremendous enthusiasm.

As Dr. Bombarda and the President stepped off the platform they were surrounded by numerous members eager to grasp their hands and to embrace them. Not a few, especially the Portuguese members, fell in each other's arms and indulged in many wild and excited manifestations of their joy at finding that the Congress had proved so complete a success. Loud were the shouts, the laughter, the cheers that accompanied the President and the general secretary as they struggled through the excited and grateful crowd *from the hall to their private* office. The Congress certainly ended joyfully. Everybody seemed pleased and happy.

THE SECTIONS.

THERAPEUTICS AND PHARMACOLOGY.

Heliotherapy.

Dr. EDOUARD MASIP (Madrid) read a paper upon this subject. He began by some remarks upon the physics of light and then proceeded to give an account of the ways in which this form of energy had been utilised as a therapeutic agent. His conclusions were as follows. 1. Solar light acts in a physiological, hygienic, and therapeutic manner. 2. The thermo-photo-chemical phenomena produced upon the organism by the solar radiation can be scientifically explained by a reference to absorption and reflection, aided by refraction, dispersion, diffraction, and polarisation. 3. Synchronic vibrations between the ether (the transmitter) and our organism bring about the absorption of the solar radiations, whether thermal or actinic; asynchronism, on the other hand, causes their reflection. It is fair to suppose that a similar action can be attributed to the invisible portions of the spectrum. 4. Solar light acts upon the organism as a microbicide by *modifying* the cellular elements and by destroying the pathogenic elements. 5. The results obtained *from* solar radiation are in direct ratio to its duration and its intensity. 6. Heliotherapy produces two classes of essential phenomena upon our organism, the one of an exciting and the other of a depressing nature. By bringing about these effects we can treat a number of maladies, such as, for instance, those of the skin, gout, rheumatism, lupus, malignant new growths if they are superficial, diseases of the kidney, tuberculosis, anæmia, pharyngitis, and others. This form of energy is bound to have a place in the therapeutics of the future.

The Hypodermic Injection of Oxygen.

A paper on this subject was communicated to the Congress by Dr. J. DÓMINE and Dr. J. CHABAS, both of Valencia. They stated that, so far as they knew, the first instance of the employment of oxygen as a therapeutic agent by hypodermic administration was when Dr. Dómine used it in 1900 at Valencia. The discovery was accidental and came about owing to a faulty apparatus with which Dr. Dómine was trying to inject physiological serum in a case of typhoid fever. Air was injected as well and the results were so good that he attributed them to the oxygen. He therefore made trial of the injection of pure oxygen with great success. Dr Dómine and Dr. Chabas gave an account of various cases of disease in which the treatment had been tried. To put it broadly, it was useful in all conditions where there was either stasis of the blood current or neuritis, such as carbuncle or sciatica, or any condition in which the blood was not properly oxidised. No evil effects had ever been noted to follow the *use of oxygen. They used an apparatus consisting* of a reservoir for the oxygen which led into a wash bottle. From the wash bottle the gas passed through a tube provided with two bulbs having valves, and the last bulb communicated by a short piece of tubing with an ordinary hypodermic needle. The oxygen when injected into the cellular tissue was rapidly absorbed. It had a local mechanical action and a general chemical action.

Dr. DOYEN (Paris) read a paper upon

Proteol.

He said that the principal antiseptic powders used in surgery were salol and iodoform, but he had found that they were comparatively inert, and in searching for a substance of the same class but possessed of greater energy he had discovered proteol, a powder in which formic aldehyde was combined with casein. If three test tubes six inches long were half-filled with neutral or slightly alkaline culture bouillon, inoculated with any virulent bacteria or even with fæcal liquid, and mixed one with salol, one with iodoform, and one with proteol, it would be found that the two first gave an abundant growth in from 12 to 24 hours, while the tube containing proteol remained sterile. Compounds of formic aldehyde and casein have been already described by various writers but they all have the disadvantage of *being prepared* in an autoclave at a temperature of 100° C. or higher. temperatures at which formic aldehyde was polymerised and rendered inert, whereas proteol was prepared at the *ordinary* temperature and the bactericidal energy of the formic aldehyde remained unimpaired. Compounds of formic aldehyde with gelatin and egg albumin have *also been described* but they were open to the objection of becoming swollen by contact with the fluids of wounds and afterwards adhering like partly dried starch. *Proteol, on the other* hand, remained a powder after being wetted by the fluids of wounds and had no characteristic odour. It was well adapted for disinfecting both the surgeon's hands and the patient's skin at the site of an operation. For this purpose the powder might be mixed with the lather of ordinary soap, or it might be used in the *form* of a special proteol soap *(crême de savon au protéol).* Proteol answered well as a dressing both for the incisions in the skin left after operations and for chronic ulcers [illegible] leg; gauze impregnated with it was useful for insertion into infected cavities or as a dressing for infected wounds.

MEDICINE.

Dr. G. W. M'CASKEY (Fort Wayne, U.S.A.) read a paper on

The Action of Diseases of the Digestive Tract in the Production of Arterial Hypertension.

The splanchnic circulation was regarded as one of the most important regulatory mechanisms of the arterial tension and was closely connected with the digestive organs. Diseases of the digestive organs might affect the tension in two ways: (1) by reflex nerve influences; and (2) by the absorption of toxic products. The latter was probably the more important method. Three questions were then discussed: (1) Could chemical products in the circulation lead to prolonged hypertension and arterial sclerosis? (2) Did such products act directly or indirectly? and (3) Could the products of the intestinal flora lead to such results? Dr. M'Caskey related clinical evidence in support of his conviction that toxic absorption from the intestines led to arterial hypertension.

Dr. JULIANO MOREIRA and Dr. AFRANIO PEIXOTO (Rio de Janeiro) communicated a report on

Mental Diseases in Tropical Climates.

They summed up their observations under the following headings: 1. No pathological form of mental disease differing from that of other climates existed in the so-called tropical zones, neither amongst the natives of the country nor among the Europeans. 2. There was no relationship between the cases of insanity occurring in Rio and the other towns of Brazil and the maximum temperature of these towns. 3. There was no correlation between the climatic states (temperature, moisture, &c.) and the number of cases of insanity in the warm parts of Brazil. 4. The meteorologic and seasonal influences on the insane presented individual differences in warm climates just as they did in cold climates and no general rules on that connexion could be formulated. 5. The influence of the tropics on the nervous system of persons coming from cold climates varied with the individual but was usually associated with their modes of life and their nervous organisations. 6. There was no reason to believe that in tropical climates there was a greater frequency of psychoses connected with malaria. Their presence in malarial patients depended on other factors. 7. The climate had no influence on the symptoms of the various psychoses. The cause of any differences depended on the degree of education of the individual. A pure descendent of pure Caucasians if brought up in the interior with ignorant people would exhibit the same elementary insanity as the uneducated coloured people.

Dr. FRANCISCO FAJARDO (Rio de Janeiro) read an official report on

The Etiology and Prophylaxis of Yellow Fever.

In 1900 the American Commission had published its experiences, which had given a new direction to the study of yellow fever by demonstrating its transmission by the stegomyia calopus. The history of the triumph of Cuba over yellow fever was described; it had been accomplished by the careful methods of exterminating the mosquito adopted by Dr. Gorgas. Dr. Fajardo believed that in time there would be no cases of yellow fever in Rio de Janeiro, New Orleans, or in the zone of the Panama Canal. He summed up his conclusions thus: 1. Although Sanarelli's works had not received scientific sanction with regard to the cause of yellow fever they were a remarkable scientific contribution inasmuch as they shed great light on the pathological anatomy of the disease. 2. Up to the present insignificant benefits had arisen from the recent study of yellow fever with regard to its diagnosis, prognosis, and treatment. 3. The etiology of yellow fever had not so far been discovered definitely but recent research had been of value in pointing out the direction for future work; this had been done by the American commission and the Pasteur mission. 4. In Brazil the obstinate and prolonged struggle against the mosquito in general and against the propagation of yellow fever in particular would soon banish the disease from Brazilian territory, as was witnessed by the work effected in connexion with the discovery of the epidemic sources in Rio. 5. Simple transmission of yellow fever by the stegomyia could occur during the day between 9 and 3 o'clock, though rarely. 6. To-day the prophylaxis of yellow fever rested on scientific facts and could be applied everywhere with a satisfactory result.

Dr. AARAO FERREIRA DE LACERDA (Oporto) read a paper entitled—

Some Observations on the Intensive Mercurial Treatment of General Paralysis.

From February, 1904, to March, 1905, he had, in conjunction with Dr. Magalhaes Lemos, experimented therapeutically in 15 cases of general paralysis, in accordance with the precepts set forth by Leredde in his book, "The Syphilitic Nature and the Curability of Tabes and General Paralysis." In 11 out of the 15 cases syphilis had undoubtedly been in operation, in one alcoholism only was present, in one the history was uncertain but syphilis was probable, and in two no history could be ascertained. All were marked cases of general paralysis, having passed through the early stage of the disease. The time elapsing between the syphilitic infection and the onset of general paralysis had in 13 of the cases varied from five to eight years; in two cases it had been over ten years. The following treatment had been administered: (*a*) First mercurial treatment from Feb. 14th to May 13th, 1904, with an interval of rest from March 28th to April 6th. Intramuscular injections of benzoate of mercury every second day and later daily in doses of four and a half, increased to 11, milligrammes. Then followed a month of rest. (*b*) Second mercurial course from June 13th to July 6th; injections of hermophenyl daily, rising from one centigramme to 12 centigrammes dose. After an interval of ten days' rest iodide of potassium was given after three meals daily, the dose being increased from one gramme to 12 grammes daily. After an interval of 33 days the second course of iodide of potassium was commenced. A daily dose of three grammes was gradually increased to 12 grammes. An interval of 65 days was then allowed. (*c*) The third course of mercurial treatment was started on Jan. 27th and lasted to March 3rd, 1905. Intramuscular injections of hermophenyl were given, at first every second day and then daily, in doses increasing from one to 12 centigrammes. Detailed accounts were given of the symptoms of the 15 cases and the results of treatment were not encouraging. Treatment by mercury had always been stopped if the patient lost weight or developed albuminuria or an oscillating temperature. The conclusions arrived at were 1. That mercury can be administered in the quantities indicated without danger of skin manifestations, stomatitis, or intestinal disturbance. 2. In each course of treatment not more than 22 injections should be made and they must be injected deeply into the upper third of the buttock. 3. Iodide of potassium in all cases led to tachycardia and feeble pulse. 6. The biniodide of mercury was an excellent preparation for this method of treatment. The hermophenyl produced no pain and was easily managed. 7. The lack of success in the cases described was explicable because none of them had been treated in the initial stage of the disease.

Dr. ANTONIO MUÑOZ RUIZ DE PASANIS (Cazorla) read a paper on

Cardiac Arrhythmia.

He said that arrhythmia might be either organic or functional, the former being due to causes which affected the structure of the cardiac muscle and the latter being brought about through the agency of the nervous system. There were, however, some disturbances of the innervation of the heart which did not give rise to arrhythmia. Any interference with the pneumogastric or the great sympathetic would, for instance, produce not arrhythmia but tachycardia or bradycardia. It was not at present possible to classify the various forms of nervous arrhythmia in accordance either with clinical observation or physiological experiment. The mechanism of arrhythmia could be explained in conformity with the distribution of the muscular fibres in the auricles and ventricles, and their mode of action. The muscular fibre of the heart always contracted rhythmically, rhythmic action being one of its essential properties, but rhythmic action did not imply the co-existence of synchronism, because two organs might move rhythmically although not synchronously. For two organs to move synchronously there must be some link connecting them, and there must also be a cause which determines the instant when the movement begins. Now the auricles and ventricles are structurally connected by their muscular fibres, and in order that they may move synchronously the nervous system must supply both with the necessary stimulus. When this stimulus was not supplied to each at the same instant, whether from mutual interference of the nervous currents or from inhibition of one of the nervous fibres of one auricle or one ventricle, the result was the production of nervous or functional arrhythmia.

The Treatment of Sundry Nervous Diseases by Methodical Exercises.

Dr. **MAURICE FAURE** (La Malou) read a paper upon this subject. The paper dealt with ataxia, paraplegia both spastic and otherwise, hemiplegia, "tics," cramps and tremors, functional paralyses, various forms of sclerosis, and infantile paralysis. In all these forms of disease or results of disease except sclerosis graduated exercises carefully carried out had been found to do good, although the results were not all equal in every class of case. The best and most lasting results had been obtained in ataxia. In hemiplegia they were not so lasting and in paraplegia and the other diseases considered there was not enough experience to found any definite opinion as regards the duration of any benefit which might accrue. In hemiplegia the treatment, massage and passive movements, ought to be begun as soon as possible after the stroke. In this way the pain, the atrophy, and the malposition which were so often the results of hemiplegia might be almost altogether avoided or at least minimised. If the treatment was only begun after the appearance of arthritis, of contractions, of atrophy, or of malposition but little good could be hoped for.

PEDIATRICS.

Dr. **OSCAR VULPIUS** (Heidelberg) read a paper upon

The Treatment of Infantile Spinal Paralysis.

He said that he would confine his remarks to treatment by means of a portable apparatus and to treatment by means of arthrodesis and tendon transplantation. With respect to the wearing of an apparatus his opinion was that its disadvantages exceeded its advantages and that the use of any such appliance ought to be avoided as much as possible. Good results were, however, obtainable by arthrodesis in cases when there was either total paralysis of all the muscles in connexion with a joint or when so little power remained that no control could be exercised over the movements of the joint. Dr. Vulpius has very often performed this operation on the ankle, the knee, and the shoulder, but he has, on the other hand, avoided the production of ankylosis in the hip-joint, the elbow, and the wrist. In the operation he exposed the articular surfaces freely and removed the cartilage so that the bone appeared here and there. In the case of the shoulder he sutured the two bones with silver wire but in the other joints he allowed ankylosis to take place naturally, maintaining fixation, however, by means of a well-fitting plaster splint worn for at least three months. In the ankle the uniform result was firm fibrous ankylosis of the joint in the rectangular position. In order to keep the foot raised it was well also to shorten the three anterior muscles of the leg and to fix them to the periosteum of the tibia. An unsuccessful result was rare but was sometimes caused by hypermobility of the other articulations of the bones of the foot. Flat-foot might occur if the patient began to walk too soon but this seldom happened. In the knee the articular surfaces must be freshened most freely, otherwise there was likely to be not only imperfect fixation but a tendency to flexion of the joint from contraction of the tendons. After the completion of the arthrodesis it was therefore well to resect the flexor tendons and to suture the extensors in a position of tension. Dr. Vulpius had never known hyper-extension to occur. When both knees were affected he performed arthrodesis on only one and fixed the other in a portable apparatus. Arthrodesis of the shoulder should be performed only when the muscles of the forearm were sound and when the mobility of the hand was hardly, if at all, affected. The ankylosis ought to bring the arm into a position of abduction and elevation. The foregoing procedures were intended only for the relief of total, or almost total, paralysis. In partial paralysis, which was much the more frequent of the two, he strongly recommended tendon transplantation. So far as possible he employed total transplantation, using the whole of the sound muscle and tendon, but when partial transplantation was necessary he divided the tendon quite up to the muscle in order to insure the functional independence of the transplanted part.

PSYCHIATRY, NEUROLOGY, AND CRIMINAL ANTHROPOLOGY.

General Paralysis in Spain.

Dr. **RODRIGUEZ-MORINI** (Barcelona) read a paper entitled "A Contribution to the Clinical Study of General Paralysis in Spain." He commenced by giving a brief account of the recognition of the malady as a definite and separate disease and then discussed the incidence of the disease, its etiology, and its predominant clinical forms. His conclusions were that general paralysis was a disease of such interest that every fact concerning it which it was possible to collect should be classified in order to throw light upon the many disputed points which still exist. Spanish physicians have up to the present contributed but very little to the subject. The statistics of mental diseases in Spain as at present published give little indication of the true frequency of general paralysis. Dr. Rodriguez-Morini, who is the physician in charge of the asylum of San Baudilio de Llobregat at Barcelona, had founded his paper upon facts noted by himself in the asylum where he was in charge and upon information obtained through the courtesy of the heads of other Spanish asylums. From the figures obtained he was able to say that the proportion of general paralytics among the male asylum patients in Spain was from 5 to 6 per cent. on the average. In the north of Spain the percentage ran up to 8 per cent., a rise which was probably due to the greater frequency of drunkenness in the north as against the south. Among the female inhabitants of asylums the proportion was only 1 per cent. The ages of the patients were, as a rule, between 32 and 48 years. General paralysis scarcely ever appeared before the age of 25 years or after the age of 50 years. It was far more common in townsmen than in countrymen, more common among the married than among the single, and more common among members of the liberal professions than among artisans and workers with their hands. In 90 per cent. of the cases syphilis was the chief etiological factor. To alcohol were due probably 8 per cent. of the cases and in 2 per cent. no definite cause could be assigned, although it seemed probable that some acute infection was at work.

DERMATOLOGY AND SYPHILIS.

Dr. **SUAREZ DE MENDOZA** (Paris) read a paper on

Syphilis of the Intestine.

He pointed out that little has been written on this subject and therefore he described a case under his own care. A man, 62 years old, complained *inter alia* of a persistent diarrhœa which had lasted eight years and had resisted all treatment. As the patient had lived for many years in the tropics a diagnosis of "tropical diarrhœa" was made and suitable treatment was employed; much improvement followed, though as soon as the treatment ceased the diarrhœa returned. In spite of the absence of a syphilitic history, Dr. de Mendoza decided to employ antisyphilitic treatment and gave hypodermic injections of hermophenyl, at first two centigrammes a day, increasing to eight centigrammes daily. Ten days after the commencement of treatment the diarrhœa was much better and after the thirtieth injection the patient was well; noises in the ears and some laryngeal trouble from which he had suffered also improved. Iodide of potassium was then given (four grammes a day) and a month later the patient ceased treatment. He was advised to have every three months 20 daily injections of hermophenyl, followed by 20 days' treatment with the iodide. A year later he remained well. Dr. Mendoza has collected the literature of the subject and he finds that the first case diagnosed as syphilitic affection of the intestine seems to have been described by Cullerier in 1854, but Monteggia in 1794 described a necropsy in which syphilitic ulceration of the whole of the large bowel was present. From a consideration of his own case and of those recorded Dr. Mendoza comes to the following conclusions: (1) That intestinal syphilis is much less rare than is ordinarily supposed; (2) it affects especially the end of the small intestine and the large intestine; (3) the symptoms are few and indefinite and the diagnosis is difficult; and (4) if a diarrhœa proves rebellious to ordinary treatment antisyphilitic measures deserve a trial even though there is no history of syphilis.

SURGERY.

Dr. A. **CODIVILLA** (Bologna) read a paper on

The Indications for the Transplantation of Tendons.

His opinions were founded on the results of 415 operations which he had performed. Many of the cases had been followed up and examined from time to time to see whether the results were permanent. He did not employ the operation for certain cases in which he formerly used it. His experience had taught him that it was necessary to have more muscular force available than he used to think necessary, for a certain part of the power was lost in consequence of the new mechanical conditions to which the tendons and muscles were subjected Unless attention be paid to the importance of having a distinct excess of available muscular power it would be useless to expect any movements after operation. Muscles already weakened by disease were useless for transplantation of tendons. For spastic paralyses also much good might be done and athetotic and choreiform movements might wholly cease on transplantation of tendons; but in all these cases the same rule held good that there should be a notable excess of power in the muscles above that which was apparently required. If this excess was not present no movement could be expected and so the method was then to be compared with other methods of joint fixation. Age offered no absolute contra indication, but it must be borne in mind that the trophic condition of the muscles and functional adaptability became less with increasing age. Site had little influence, but the lower leg and the forearm were the most favourable regions of the body. As to the results, he considered that in suitable cases the method was without a rival Possibly in the future plastic operations on nerves might in part replace the transplantation of tendons, but not at present

Dr. **MILIAN** (Paris) read a paper on

Leucoplakia.

He commenced by pointing out the lack of agreement amongst authors as to the definition of the word but he applied it to all persistent white patches of the mucous membranes. The white colour was not due to the presence of any horny layer or even to the presence of eleidin; neither was it caused by any hardening of the derma. It was due to a change in the cells of the mucous membrane. They had undergone a chemical change, the proteid having become white; and this might be compared to the white appearance of some ascitic fluids. Histologically there were present hypertrophy of the cells, a basophil condition of the protoplasm, slight interstitial œdema, and nuclear hyperplasia. These conditions were the result of irritation; they were associated with inflammatory changes in the derma of the mucous membrane. Leucoplakia was an indication of a functional superactivity and not of a degeneration. It was the result of irritation by toxic substances. Leucoplakia was generally secondary to changes in the derma (secondary leucoplakia) but rarely it constituted the sole abnormal condition (primary leucoplakia). Many lesions might give rise to leucoplakia, such as papules, erosions, and ulcerations. As to its etiology there were certain conditions, such as epulis, psoriasis, and balanitis, which never gave rise to leucoplakia, whilst there were others, such as lichen planus, lupus erythematosus, and syphilis, which might cause it The question arose, Were there ever any cases of "idiopathic leucoplakia"? Probably not; all cases apparently idiopathic were fairly certainly syphilitic in origin. There were many arguments in favour of this, such as the great resemblances between lingual syphilis and leucoplakia of the tongue, the presence of a syphilitic history in 80 per cent of the cases of so-called idiopathic leucoplakia; and especially the facts that a careful examination would show the presence of syphilitic characters and that mercurial treatment would cure nearly all of them. As a predisposing cause the arthritic diathesis was of some importance and local injury, due to eating and smoking, had some effect. The pathological change present was a keratinisation of the mucous layers and a sclerosis of the derma. The colour of a patch of leucoplakia varied from a bluish-white to a milk-white and the surface might be smooth or ridged or papillary. An elaborate table was given of the varieties of leucoplakia in relation to the cause and appearance. Dr. Milian said that though there could be no doubt that epithelioma might develop from leucoplakia yet he could give no definite explanation of the transformation. As to treatment, when all the forms due to lichen planus and similar conditions had been put aside—for they needed their special forms of treatment—there remained only cases of syphilitic origin, and at least 80 per cent. of the cases were syphilitic, when antisyphilitic treatment should be employed. Locally the avoidance of all forms of irritation was important, such as strong tooth powders and caustics. The mouth should be kept clean by the tooth-brush and soothing gargles. Alcohol, wine, and tobacco should be avoided. Internally iodide of potassium was useless. Mercury should be given hypodermically. One important point was that the treatment should be long-continued and six months was the minimum for continuous treatment and for two or three years an intermittent treatment should be carried on. Gray oil and calomel were the only suitable substances for injection, but a keen look out should be kept for signs of poisoning. At the end of three months there should be an interval of four weeks and then the treatment should be resumed. By this method of treatment the ulcerations healed, the deep lesions softened, and the tongue regained its suppleness. The leukoplakia diminished in extent but some patches would always remain. The tongue should always be watched so that surgery might intervene as soon as a suspicion arose of a malignant transformation. There was much to be said in favour of a surgical removal of the patch in the pre-cancerous stage but a preliminary mercurial treatment should always be employed and the excision should not be limited to the epithelial layer. Prophylactic treatment was of great importance and leukoplakia should be prevented by a thorough mercurial treatment of all syphilitic lesions.

LARYNGOLOGY, RHINOLOGY, OTOLOGY, AND STOMATOLOGY.

Professor **RAYMOND DE LA SOTA E LASTRA** (Seville) read a paper upon

The Diagnostic Difference between the Lesions of Tuberculosis, Syphilis, and Cancer in the Larynx.

The conclusions which he arrived at were as follows. 1. Tuberculous laryngitis is a hereditary complaint and appears at an early period of life. Syphilis is also hereditary but the laryngeal infection is found more usually in the acquired variety. Cancer is not hereditary nor present before the age of 40 years. 2. Tuberculous disease of the larynx is always accompanied by other tuberculous lesions. The same applies to syphilis, while in cancer the reverse obtains. 3. Disturbance in the voice is one of the cardinal features in tuberculosis, with dysphagia, night sweats, &c. In syphilis the general health is usually good, though sometimes dysphagia is present. Cancer may exist for a long time accompanied only by hoarseness. After ulceration has set in a horrible stench is observed, with cachexia and referred pains. 4. It has usually been considered that these referred pains are present only in cancer, but they are also present in a less degree both in tuberculosis and syphilis. 5 The odour exhaled in cancer is unmistakeable. The expectoration in syphilis is very fœtid but different in character, while the exhalations in tuberculosis are not offensive. 6 Deformity of the thyroid cartilage is more pronounced in cancer than in tuberculosis and syphilis. In syphilis this frequently represents the carapace of the tortoise. 7. In tuberculous laryngitis more or less congestion is seen on microscopic examination; at other times there is anæmia of the mucous membrane showing ulceration of special parts, especially the arytenoid. 8. In lupus the point of infection is the epiglottis. In syphilis during the secondary period great hyperæmia is present, together with multiple small ulcers. In the tertiary period gummatous tumours are found either of the same colour as the surrounding tissue or of a more yellowish hue. Cancer commences by a tumour on the cord, usually posteriorly and to the left, extending into the arytenoid region near the cord, and eventually involving the whole of the tissues of the organ.

Dr. F. J. **MOURE** (Bordeaux) read a paper upon

Different Forms of Suppuration in the Maxillary Antrum.

The varieties of suppuration in the maxillary antrum he classed under two cardinal headings—acute and chronic. The acute, he said, are (1) simple or catarrhal; and (2) infectious or osteomyelitic. The chronic are (1) of dental origin—(*a*) from direct infection or empyema, and (*b*) from suppuration of dentigerous cysts; (2) of nasal origin—(*a*) from muco-purulent infection, and (*b*) from atrophic rhinitis, caseous rhinitis, or syphilitic rhinitis; (3) from foreign bodies; and (4) from trauma. In the simple forms of the acute disease there is no pain if the orifices of the antra are large and the pain is increased in proportion to the smallness of the opening. Photophobia, a sensation of weight, with perhaps some œdema of the face and of the lower eyelid, are the most marked features. In the infectious variety the pain is more intense and of neuralgic violence and usually unilateral. It is present especially in the region of the eye on the same side. Photophobia and lacrymation are marked, the temperature is raised, and there are considerable swelling and œdema. Mastication is difficult. Death not infrequently occurs as the result of an intense infection, but this is fortunately rare. Immediate operation is advised. In the chronic cases dental infection is either followed by the disappearance of the epithelium lining the cavity or abundant proliferation of the tissues in the neighbourhood of the diseased teeth. The symptoms of the condition, as also the treatment, were, he said, too well known to need further remark. The point of chief interest in regard to suppurating cysts is that the diagnosis is usually made at the time of operation. The traumatic cases and those caused by foreign bodies are usually the result of malhandling on the part of the dentist, either fracture of the alveolus, penetration of the sinus by forceps or an elevator, or the forcing into the cavity of a piece of bone.

Mr. C. E. WEST (London) read a paper on

The Occasional Influence of Adenoids and Aural Foreign Bodies on the Causation of Epilepsy.

The views of Sir William Gowers with regard to antecedent causes of epilepsy were briefly given, and the general view was expressed that there is a wide range of degrees of cortical readiness of response, passing up from those conditions known as normal to those of pathological instability, when powerful or continued irritation may succeed in firing off a generalised explosion. Finally, reference was made to those cases in which the degree of instability is so great that a stimulus so faint as to defy detection, or perhaps the mere accumulation of some product of living processes, is sufficient to cause the onset of an epileptic fit. Working on this hypothesis the possibilities of naso-pharyngeal obstruction, which so frequently produced delayed and impaired intellectual vigour, and was not uncommonly connected with rickets, were reviewed as possible factors in the causation of epilepsy, and reflex conditions, such as asthma, polypi, cough, and granular pharyngitis, were quoted. Several cases were given, showing that after removal of adenoids epileptiform convulsions, which were previously present, had ceased. As regards foreign bodies in the meatus, however, there seemed, said Mr. West, to be a question as to whether the effect of these foreign bodies was an exaggerated attack of aural vertigo or an epileptic fit, though several cases were quoted as evidence of its being the latter.

Dr. GEORGES MAHU (Paris) read a paper on

Injections of Paraffin Wax in Rhinology.

The first portion of this communication dealt with the literature on the subject up to the end of last year. Interstitial injection of vaseline and paraffin, submucous injection of paraffin, and several other methods were considered. The injection of vaseline, said Dr. Mahu, was soon abandoned for various reasons, the principal one being its rapid absorption, and hard paraffin took its place. The effect of the presence of paraffin in the tissues was then dealt with. Foreign bodies were considered, physical, mechanical, toxic, and septic. A large number of instances were quoted in which accidents had occurred under each of these headings, but these could most effectually be avoided by the most absolute asepsis, the employment of paraffin melting at a high temperature, and a careful limitation of the injection. When the injection was made into the turbinate bone, however, the employment of cold injections was recommended. The next consideration was as to whether these injections were permanent. If a hard wax were used, or one melting at a high temperature, relative permanence of the effect produced was insured. External injections with cold paraffin were recommended for congenital deformities, such as malformations of the nose, slight clefts in the hard palate, and for acquired deformities, such as the destruction of the nose following syphilis, malformations produced by cicatricial contraction, and in cases in which part of the nose or cartilage had been lost by trauma, deformities following surgical intervention, especially in connexion with the accessory cavities, and hemiatrophy of the face. The injections should not be used when the person was suffering either from an acute or a chronic illness or when the tissues into which the injection was to be made were bound very tightly down into the subjacent bone. The technique was very carefully considered. Intranasal injections were also reviewed.

Dr. JAIME DE LOSADA read a paper on

The Treatment of Pyorrhœa Alveolaris.

The first class of case was characterised by the inflammation of the edge of the gum produced by the mechanical irritation of tartar. The second class was distinguished by the complete absence of mechanical irritation and the malady was largely confined to the periosteum. In the first class the affection originated in the region of the root, the remainder of the fang being normal. The prognosis was favourable and the treatment consisted in the removal of the cause of irritation, curettage, and the cleaning away of every particle of foreign matter, proceeding as far down the fang as was necessary and cleaning out all pockets with a jet of hot water containing some germicidal and astringent in solution, such as trichloracetic acid. In the second class the prognosis was usually unfavourable, but treatment should be commenced at the earliest possible date. It should consist chiefly of general hygiene of the mouth and constitutional remedies for arthritis should be administered. Curettage and germicidal and astringent irrigations should also be employed in these cases. Perchloride of mercury was especially recommended as an antiseptic. A third class of case was distinguished by degeneration and increase of periosteum of the fang, frequently accompanied by the formation of calculi, together with the presence of urates and calcareous plaques. The prognosis here depended largely upon the intensity of the gouty diathesis and the treatment should be principally constitutional. The local treatment was much the same as that recommended in other cases.

Dr. LUDGER CRUET (Paris) read a paper upon

The Choice of an Anæsthetic in Tooth Extraction.

After a very detailed review of all antiseptics, local and general, the following conclusions were arrived at. The employment of anæsthesia was absolutely legitimate for the extraction of teeth, with the view of abolishing pain. In such a case there was justification for using either general or local anæsthesia, but general anæsthesia should be reserved for difficult cases and multiple extractions. Chloroform or ether were the best anæsthetics, but there was nothing against the use of other substances with appropriate indications. Brief general anæsthesia in a difficult subject was better than local anæsthesia. Bromide of ethyl and chloride of methyl should be given in preference to nitrous oxide gas. Local anæsthesia was preferable in the vast majority of cases. Freezing alone was generally insufficient, but it might be employed to intensify the effect of an anæsthetic injected subcutaneously. The local anæsthetic for choice was hydrochlorate of cocaine.

Professor W. D. MILLER (Berlin) read a paper upon

The Present State of our Knowledge with regard to the Causation of Dental Caries.

There are, he said, two stages of destruction of the teeth during caries: (1) calcification of the enamel and (2) disappearance of the dentine; and under these two headings all the work done by previous writers up to the present time was carefully considered and reviewed.

HYGIENE AND EPIDEMIOLOGY.

A Precursor of Hygiene.—Professor Loeffler's Discoveries.

Though the sections as a rule have been but poorly attended an exception must be made in honour of the Section of Hygiene. Here there were moments when it was not easy to find a seat. It is true that only a small room was allotted to this section and that was a mistake. In many of the other sections members are prone to think that they have little or nothing to learn. They do not feel very desirous to hear someone they do not know read, probably so badly as to be unintelligible, a paper that is too long and contains little that is new. Therefore unless the member expects to be called upon to read a paper himself or knows that the papers about to be read are really worth hearing he is likely to prefer sight-seeing, especially in so attractive a town as Lisbon. But those who attend the Section of Hygiene are often animated by other than mere professional motives They have certain reforms, legislative measures, and other public matters to press forward. They attend the section, not merely because of the scientific interest of the papers and discussions but as a public duty. Therefore the attendance is larger and the members are, in many instances, very much in earnest Nevertheless, even this section did not get to work on the opening day till long after 9 o'clock, though the hour of meeting was 8 30 A.M., and it was not really well attended before 10 A.M. The proceedings were opened on the morning of Friday, April 20th.

The President of the Section, Dr. RICARDO JORGE, general inspector of public health in Portugal, read an introductory address in which he pointed out that man in his ignorance was the principal creator of insanitary conditions and the principal obstacle to their removal. With Herbert Spencer, he thought there should be a physical morality and the respect of health should be accounted a public and a private virtue. To sin against the laws of health was as great an evil as to sin against the laws that protect property. Fortunately, a new social science was coming into existence. They no longer agreed with the optimist that everything was for the best in the best of all possible worlds, but rather with Goethe who sadly wrote that, as we live but once, we should make that life as durable and healthy as possible Man was a social being, yet the worse evils arose from living in common, therefore it was the common business of all to remedy these evils It was this collective action for the preservation of health which constituted social hygiene. Great progress had already been achieved on these lines and he claimed that a Portuguese practitioner was among the earliest founders of modern hygiene. In 1756 Dr. Ribeiro Sanches wrote "A Treatise on the Preservation of the Health of the People," and urged that it was the duty of the State to enact laws to protect the health of the people. A medical man could not fight epidemics if the State did not endeavour to remove the cause Dr. Ribeiro Sanches, in the eighteenth century, studied the influence of air, soil, and water on the health of populations and how they might be contaminated. He dealt with medical geography and foresaw the connexion between damp soil and insects with malarial and yellow fevers He also dealt with the sanitation of dwellings in large towns, the necessity of wide streets and the quick removal of dirt. He proposed a control over dwellings by municipalities and even advocated sewers He denounced the insanitary conditions of barracks, prisons, and hospitals, pleaded for cleanliness and fresh air, and wrote strongly against what he called "smothered air" He demanded that the clothes and dwellings of the sick should be purified and mentioned tuberculosis as one of the diseases where such precautions were necessary. Instead of quarantine he proposed a rigorous cleaning of the ships; and what is more surprising urged that ships should be fumigated till all the insects and rats were killed. When it is remembered that all these reforms were proposed 150 years ago by this Portuguese practitioner, and that now we are only beginning to realise them, the President concluded that it was more easy to introduce injurious than beneficent things.

The President asked permission to display a portrait of Dr. Ribeira Sanches, who was the author of the first book on public and preventive medicine, and begged leave to place the opening sitting of the section under the auspices of this glorious Portuguese ancestor.

The section now elected its honorary presidents, voted that a telegram of sympathy should be sent to Madame Curie and then called upon Professor LOEFFLER to make a communication on[1]

A New Method of Preventive Inoculation against Foot-and-Mouth Disease.

Some years ago Professor Loeffler prepared a preventive serum by injecting horses with increasing doses of a virulent lymph which is to be found in the vesicular eruptions of sick animals. With doses of from 10 to 20 cubic centimetres of this serum hogs and sheep are perfectly protected against infection for from four to six weeks. The duration of the immunity produced by the serum was found to be much shorter for the bovine species, because the serum of a horse, foreign to the body of a bullock, is eliminated in a comparatively short time. By treating bullocks cured of the illness in the same manner as horses with increasing doses of lymph Professor Loeffler obtained a preventive serum that was also excellent for the bovine species. But as it was not possible to cultivate artificially the infectious agents of the malady it was necessary to obtain the required lymph drop by drop from the infected animals. That is why the price of the serum is somewhat high. To immunise animals in as inexpensive a manner as possible it was necessary to find a method of active immunisation with an attenuated lymph. Last year Professor Loeffler published an account of such a method. A certain amount of virulent lymph mixed with a certain quantity of preventive serum was injected under the skin. The best results were obtained from this mixture of $\frac{1}{75}$th cubic centimetre of virulent lymph and half a cubic centimetre of preventive serum. Three weeks after the injection of the mixture the injected bullocks supported $\frac{1}{50}$th cubic centimetre of virulent lymph. 15 days later an injection of $\frac{1}{10}$th cubic centimetre of lymph and after another 15 days $\frac{1}{75}$th cubic centimetre of lymph was given. Then only had the animals acquired an immunity that enabled them to resist the disease itself. This method did not cost much but it was necessary to inject the animals four times to reach the required degree of immunity. These repeated injections gave rise to many practical difficulties Therefore another effort was made to discover a method by which one single injection would suffice. Professor Loeffler succeeded in finding this method in the following manner. It was not possible to cultivate the infecting agent artificially; it had to be cultivated in the body of animals susceptible to the disease. The disease of the bullock is transmitted to the bullock by means of the lymph taken from the vesicles, then after three or four inoculations the lymph no longer produces any effect. The inoculated animal does not become ill. The result is the same if the inoculations are from hogs to hogs. The series of inoculations become more lengthy if bullocks and hogs are inoculated alternately. The only animal in the body of which the virus may be preserved is that of a sucking-pig aged about five or six weeks. In trying the lymph obtained from sucking pigs on bullocks it was observed that the bullocks, which are really more susceptible to this disease than hogs, stood rather strong doses of this lymph—$\frac{1}{25}$th or even $\frac{1}{10}$th cubic centimetre—without contracting the disease. The lymph therefore was attenuated in its virulence so far as its action on the bovine species is concerned. Unfortunately, this attenuation was not of a stable nature but it became stable if cultivated in sucking pigs of the same race. After an injection of $\frac{1}{75}$th cubic centimetre of this lymph the bullocks obtained an immunity that was well marked and durable. To avoid any risk or danger of infection the animals inoculated with the lymph received at the same time an injection of a small quantity of preventive serum, from ten to 20 cubic centimetres, under the skin and in some other part of the body. This new method was tried on several dozen bullocks at the experimental station of the Institute of Hygiene at Greifswald. Apart from the practical consequences, the scientific importance of the experiments consists in that the infecting agent of one disease attacking two different kinds of animals can be attenuated in its virulence for the one kind of animal because it has been cultivated only in the other kind of animal. By artificial cultivation in the bodies of one sort of animal the agent adapts itself to that species and is rendered less likely to infect the other species. Thus it is possible to profit by this agent attenuated in the first species to make with it preventive inoculations in the second species, even though the latter is by nature much more susceptible to the disease than the first species. Thus we have here a certain analogy with vaccination. The infecting agent of small-pox is transmitted to the calf and is cultivated in the body of the calf. By this process it is so modified that it only produces in man a local pustule. That is why it is possible to make preventive inoculations in man against small pox. There is an analogous relation between human and bovine tuberculosis. The bacillus of tuberculosis cultivated naturally and frequently in man loses its virulence for the bullock and the bacillus cultivated constantly and naturally in the bullock loses its virulence for man. Thus we may profit by the human bacillus to make preventive inoculations in bullocks against the bovine bacillus, and *vice versâ* probably it will be possible to immunise man with the bovine bacillus against infection from the human bacillus. The important result of the new researches in regard to inoculations to prevent foot-and-mouth disease is then a fact verified experimentally. It is possible to obtain a vaccine by adapting artificially the agent of a disease attacking two species, cultivating for some time this agent in the body of one species and inoculating with it the other species.

---

[1] This is the account of the communication written by Professor Loeffler himself for the archives of the section which he very kindly lent to our Special Sanitary Commissioner, who reported this section for us, so that he might translate it into English.

Disinfection.

The next subject discussed was the report by Dr. GUILHERME ENNES, director of the disinfecting station at Lisbon. He urged that isolation without disinfection would fail in its purpose. But disinfection should not be intrusted to private business firms; it must be carried out under strict public control. Nor should private, charitable, and other institutions be allowed to instal on their premises disinfecting stoves without submitting them to inspection and only employing that which the Government recognised as efficacious. Such stoves should have self-registering thermometers that would show the degree of heat in the interior of the stove and how long that heat had been maintained during the operation of disinfecting.

At the conclusion of this report a few words were said as to the necessity of giving financial compensation to poor home workers—small laundresses, dressmakers, and others—whose business was often almost destroyed by the alarm caused when their premises were disinfected. Diseases would be concealed if there was a serious risk of the persons affected losing their means of livelihood. This was generally approved and the reporter explained that in Lisbon compensation was given when bedding was burnt or other objects were destroyed. It was agreed that a sanitary law to be effective must be thoroughly understood and approved by the mass of the people.

The section then adjourned.

SOME GENERAL CONSIDERATIONS AND THE FESTIVITIES OF THE WEEK.

(FROM OUR SPECIAL COMMISSIONER.)

Lisbon, April 27th.

The Congress is over and great credit rests with the Portuguese organisers and notably with the general secretary, Dr. Miguel Bombarda, who is evidently gifted with the genius of organisation. It is not so easy to see in what manner the foreign nations contributed to the success of the Congress. The foreign Governments certainly did their share in sending numerous official representatives who were distinguished by the gold braid with which the artistic silver Congress badge was suspended to their coats. There were also many who wore a silver braid and this testified that they were the delegates of faculties of medicine, schools, or learned societies. The ordinary member had a light blue-and-white ribbon for his badge and these are the colours of the town of Lisbon. As compared to other congresses the latter category of members were not as numerous and this greatly facilitated the work of organisation. But this raises the very important question of what these congresses are supposed to represent. For instance, the grand committee which allotted the Paris and Moscow prizes consisted of the Government representatives and of the presidents of the sections. Can these gentlemen be taken to represent the medical profession? This profession consists in the main of general practitioners, whereas the eminent and distinguished members of this committee were medical men who, for the most part, had very little to do with general practice. So long as the congresses are mere demonstrations of international interest and sympathy with the scientific studies of the nations represented the above considerations are not of much practical importance. But motions are now passed and efforts are made to influence legislature—not to any great extent as yet, but this will grow. Then it will be a matter of imperial necessity to deal with the question as to how votes should be taken and how those who govern these congresses are to be appointed. It is more especially the section dealing with sanitary matters and with the prevention of epidemics that touches most frequently on matters of medical politics or social legislature. This is precisely the one section which throughout was well attended and where the greatest number of motions were carried. Of course, this is quite natural. Hygiene supplies a scientific motive for legislation, and hygiene unsupported by legislation could not do much good. But if this is admitted, then it must also be admitted that it is necessary to see that opinions which are given out to the whole world in the form of motions should be endorsed by, and emanate from, truly competent and representative bodies. Again, in the hygiene section several sanitary engineers and other specialists on sanitation were admitted though they were not medical men. This is right enough, but an awkward question is opened up thereby. If sanitary engineers are to be admitted to the hygiene section of a medical congress, why should not any unqualified person whose work may be considered as ancillary to, or developmental of, any branch of medicine be eligible for membership. And once such a concession is made who is to distinguish in the crowd of unqualified individuals the man of science from the pretender?

CINTRA AND THE KING'S DINNER.

Looking back upon the busy week which has just elapsed and its attendant pleasures I must first regretfully explain that I was not able to join the numerous party that went to Cintra. The lavish hospitality and the magnificent gardens of Sir Francis Cook, Viscount Monserrat, came in for unstinted praise. It took place on the day of the London mail. But all accounts coincide in expressions of delight and admiration. There are also comical stories told of big medical men riding very small donkeys to reach the grounds that are some distance from the station.

On Saturday evening, April 21st, the King entertained at dinner some 200 guests. These were the delegates sent by the various governments to the Medical Congress and the members of the executive committee of the Congress. There were no speeches. It was a friendly gathering and demonstrated once more the keen interest the Royal Family has manifested in regard to the Congress. Indeed, I know personally that the King has carefully questioned different individuals who were in contact with members of the Congress so as to find out from independent sources whether the visitors to Portugal were pleased. Evidently the Royal Family is sincerely desirous that the Congress should produce a good impression on the numerous medical men who for the most part have seen Portugal for the first time in their lives and who may, on returning to their own country, give expression to their feelings on the subject.

THE NEW ANTI-TUBERCULOSIS DISPENSARY.

On Sunday, April 22nd, Congress did not sit, but the members were invited to visit the Anti-tuberculosis Dispensary in the morning. This institution is close to the water's edge, near the fish market, and in a very frequented part of the town. It is a beautiful white stone structure, looking more like a palace or a monumental museum than an out-patients' ward where a rough crowd of poor people may be expected to congregate. The object is to give gratuitous advice to all poor persons who are actually suffering from tuberculosis or who seem predisposed to this disease. There are to be morning and afternoon consultations. Seven medical men constitute the staff for this service. They will seek to classify the cases and while sending the more serious ones to special hospitals or sanatoriums will endeavour in other instances to organise preventive measures. The object is not merely medical treatment but investigation and material help. Money, better housing, and suitable food—these great preventative necessities—are to be supplied whenever the means for so doing can be obtained from various charitable funds and other resources. On the ground floor there are waiting-rooms for the outdoor patients and several consulting-rooms and operating rooms for minor operations, but there are no beds, so that in case of a more severe operation an ambulance would be required to take the patient either before or after the required operation, according to the nature of the case. Upstairs there is a place destined for a library, several committee rooms, and a large, handsomely furnished council chamber where some hundred persons could be seated, including special chairs for the King or other members of the Royal Family who, it is believed, will occasionally preside over meetings to be held here for the purpose of discussing administrative matters. Altogether, there is an air of great luxury and brightness about the place. Also, and with one very important and serious exception, much care has been shown to prevent contagion. All the angles are rounded off. The walls are of white tiles or paint, all washable, as also are the floors. The cases to keep instruments or dressings, the chairs, the tables, and the furniture in general, are of the latest antiseptic and washable style. But to several of the wash-stands fixed to the walls I could find no syphon trap or any other sort of trap. Testing one of these apparently untrapped pipes with a match and with a moistened finger it did seem as if there was an up-draught. This seemed, therefore, as if the airs from the sewer were penetrating the consulting- and operating-rooms. The closets were trapped but not the small lead pipes for carrying away dirty or waste water. If these pipes were carried through the wall to empty in the open air over a gully it would not matter but I could find no such gullies. Certainly this is a matter that will brook no delay, and before patients are admitted to this new and otherwise admirable institution measures should be taken to see to the trapping of all the small pipes. All the other and far more expensive anti-septic precautions adopted may be rendered futile if sewer airs are to pass over these beautiful glass and enamelled shelves and furniture, and this without let or hindrance, both day and night. Perhaps, however, I am mistaken and some sort of trapping exists but out of sight. In that case it is a pity that it should be concealed, and such concealment is in absolute opposition to the principles on which this institution is founded. One of its principal objects is to teach poor people those rules of health by which the prevalence of tuberculosis may be diminished. One of the first of these laws is to breathe pure air and therefore to trap all pipes which, communicating with the sewers, may be the means, in fact, indeed, are sure to be the means, of introducing into dwellings sewer airs of a more or less dangerous nature. Therefore traps should not only be employed but so placed that every-one can see them. Thus they may serve as an object lesson in practical hygiene and give a sense of security to all who would thus be able to see that proper precautions had been taken.

THE GALA BULL FIGHT.

In the afternoon the members of the Congress enjoyed a truly Portuguese entertainment. With admirable order little tickets of different colours—blue, white, red, and yellow—had been distributed and gave admittance to steamers with flags of the corresponding colour. On board there were luncheon baskets awaiting the passengers, so that there was no struggling to reach a buffet and the unpleasant incidents that sometimes result. For two hours the passengers were able to enjoy the fresh air and scenery of the Tagus, which inland widens out into a lake. At the furthest end of this lake is the village or small town of Villa-Franca and here the Tagus resumes the dimensions of a river. On both banks there were guards of honours, consisting of peasants mounted on horses and armed with poles, some ten feet long, which they use to drive the cattle. Their picturesque and bright-coloured attire and martial attitude made a pretty sight. Salutes were fired in our honour and when we landed showers of roses were thrown upon us by the inhabitants who lined both sides of the streets. From almost every window there hung some beautiful silk curtains or counterpanes. Most of these were crimson or yellow damask, but some were of a rich cream silk reps most artistically embroidered with flowers of many but of subdued colours. This form of decoration imparts a luxurious aspect to the streets, and when I recalled the eye-scorching bunting displayed in England and purchased for a few pence per yard I could not help thinking that there was a good deal to be learnt even in a small Portuguese village. Then I was lost in wonderment how persons evidently of very modest means, to judge from the small and simple character of the houses or cottages in which they lived, could possibly afford to have such artistic and rich silks. To my disappointment, however, I was told that some of these beautiful silks had been lent for the occasion by wealthier people whose houses did not happen to be on the road along which the members of the Congress would pass. These persons desired to help in this manner to welcome their foreign visitors.

The bull-ring to which in triumphant procession we walked is a comparatively small and modest building but it had many thousand seats which were soon filled. The bull-fight was a very different matter from what is seen in Spain. Not only are the points of the bulls' horns sawn off but the stumps that remain are carefully padded. The horses also are ridden with consummate skill and every precaution is taken to prevent the bull touching them. Banderillas are used by the men on foot and on horseback and are planted in the neck of the bull, which irritates the bull but cannot be described as torture. Just as much skill is shown as in a Spanish bull-fight and there may be just as beautiful display of costumes, but there is no killing either of the bull or of the horses. Then there are other features, such as the game of the three horsemen, one of whom wears a rose which the other two endeavour to snatch away from him. Altogether it was an artistic display of fancy costumes, beautiful horses, excellent horsemanship, powerful majestic bulls, and of an enthusiastic, excitable, and happy crowd. The King and all the Royal family again manifested their sympathy for the Congress by honouring with their presence the gala bull-fight given in our honour.

THE GEOGRAPHICAL SOCIETY'S ENTERTAINMENT.

On Monday evening the Congress was entertained by the Geographical Society in the same great hall where the opening ceremony took place. The whole of the vast floor was occupied by members of the Congress and the two galleries by members of the general Lisbonese public. On the platform there was first the guards' band and after it had played some national music a number of men and girls from the northern province of Minho came and sang and danced in their national costumes. There was also some lantern slides giving views of the Portuguese colonies. These views were not well taken and the peasants' songs and dances were the most enjoyable part of the entertainment.

THE KING'S GARDEN PARTY.

On Tuesday evening the delegates from the various governments were received by the members of the Portuguese Government; but before this all the members of the Congress had been entertained by His Majesty King Carlos in the gardens of the Necessidades Palace. This is on the side of a hill. The original trees and bushes remain and here and there only have ornamental plants been added. A clearance for lawn tennis grounds constituted the receiving centre and here the King, the Queen, and the Queen Mother walked round and talked to all who came near, thus evincing interest in the Congress, its work, and its members. In different parts of the grounds there were buffets, some for tea and light refreshments, others for wines and more solid fare. The weather was splendid, with blue spotless sky and sunshine, showing off the uniforms and the ladies' dresses in the full brightness of their colours. It was a picturesque sight and gave opportunities for many pleasant conversations and friendly greetings.

THE RECEPTION AT THE TOWN HALL.

On Wednesday evening it was the turn of the municipal authorities to manifest in honour of the Congress. This they did at their own town-hall. On approaching this building, which possesses a most artistic and harmonious frontage, I was amazed by the vast crowd filling the square where the municipal buildings stand. On entering I was likewise surprised by the size of the State stairs and the beauty of their decoration. In the corners there were cascades of giant lilies; over the flat surfaces hung enormous garlands of roses, perhaps 20 feet in length and two to three feet in circumference. Truly it was easy to realise that we were in a land of flowers. Horse guards lined the stairs, so that what with flowers and uniforms but little could be seen of the walls. All round these central stairs there are a succession of saloons. At first I was astonished to find all the windows open and a large number of persons standing by them as if to get the fresh air. This, however, proved to be no newly conceived love of ventilation but the anticipation of a fire-brigade show. In due time the engines arrived and now I began to understand why there had been so great a crowd in the square and surrounding streets. This became all the more comprehensible when the fire escapes came up. With commendable rapidity they were raised to fifth- and sixth-floor windows and balconies. Then, to the delight of the crowd, the firemen ascended and insisted on rescuing people who were quite safe and comfortable and not at all disposed to take a perilous flight on a fireman's back down a wobbly ladder into the street five or six storeys below. These were the men who had won a contest in London. They are trained by M. Fernandez and, together with a brigade from Oporto, they attended some three years ago an international contest held in London when they carried off the prize. Later when the firemen had terminated their exercises some members of the Congress also desired to show their agility and wherever sufficient room could be found there were couples dancing. There was a buffet but no speeches or drinking of toasts; in fact, no special form of reception. The municipality kept an open house, all members of the Congress were welcome, and I think I may say that they were all much impressed by the beauty of the scene and decorations. This was the last of the entertainments and on the morrow the Congress was to hold its final sitting.

THE ROYAL ACADEMY.

THOSE who enter the galleries of Burlington House hoping to find their attention arrested by important subject pictures ably painted by the leading artists of the day find themselves from year to year more liable to disappointment, and although in the exhibition now opening there will be observed many paintings of landscape admirably treated there will scarcely be noticed any among these to rank in the public esteem at all events with some which could be named of past seasons. Perhaps "Birnam Wood" (No. 246), by Mr. David Farquharson, not long an Associate of the Royal Academy but an artist of experience and sterling merit, should be esteemed as high as any. It shows a thinly wooded glade with dark tree trunks springing from a rocky soil, wreathed in the light mists that rise after the sun has sunk below the horizon. In portraiture, however, the Academy maintains as usual a high level, much as all will miss the hand of the late Mr. Charles Furze. In this class of work personal interest in the subject of the picture also attracts attention to it, and in 1906 the features of men of note are not lacking. Mr. J. S. Sargent, brilliant as ever, has not been altogether aided by the personality of his sitters, but his principal work is one of which the institution for which it has been painted should be justly proud and in which all our readers will be much interested. It is a portrait group (No. 257) painted for presentation to the Johns Hopkins University, Baltimore, and it shows Professor William Welch, Professor W. S. Halstead, Professor W. Osler, and Professor Howard Kelly grouped round a table. Their black silk gowns are relieved by the hoods of their degrees and the picture will long be remembered for its masterful treatment of sombre raiment and masculine character. The medical profession is not so largely represented on the walls as that of the law, whose members, especially when they have attained judicial rank, seem particularly given to being painted, but an admirable portrait of Sir Felix Semon (No. 37) by Professor von Herkomer hangs in the first room, not far from Mr. Sargent's picture of Lord Roberts. In the large gallery Professor Frank Clowes (No. 161) is to be seen, also on the line. He has been painted without those surroundings suggestive of his profession which some prefer, sitting on a bank in the open air with his golf clubs beside him and with a terrier lying across his knees. The portrait is that of his dog no less than of himself, as the name of the artist, Mr. Briton Riviere, R.A., will suggest. These are the principal medical portraits, but among the miniatures may be noticed (1149) Professor Robert William Reid of Aberdeen University, the name of the artist, Isabella E. Reid, suggesting that she is a lady not unfamiliar with the features which she has endowed with a character and vigour not always found in miniature painting. Mr. P. Campbell Smith (No. 1064), by Edith K. Ellis, is another good example of modern miniature work, although the ordinary everyday dress of an Englishman without the colour lent by uniform or robes smees hardly as well suited to miniature as to larger work.

Subject pictures, as has been said, are hardly so well represented as landscapes and it would be difficult in reviewing the whole exhibition in a brief note to select anything that is likely to become what is popularly known as "the picture of the year"; fortunately, however, we are only expected to look at the pictures with a medical eye and from a medical point of view. Mr. Abbey's "Columbus" (No. 143), with a flight of flamingoes flickering among the flags that surround him in his landing on the shores of America, seems hardly fitted for popularity, and Mr. F. Brangwyn's able work is not for the million. Many others whom we are accustomed to see repeat their usual subjects with variations but are none of them very insistent in their appeal to the eye. A picture which many will stand before, however, puzzling out its symbolism and discussing the not very recondite meaning of its details, is that of Mr. Sigismund Goetze) No. 710), to which he has given the title, "The Ever Open Door," with the explanatory quotation, "We brought nothing into this world and it is certain we can carry nothing out." The crowd entering the narrow portal of death, where an angel is extending a markedly cordial welcome to a Highlander fresh from his last battlefield, have abandoned in the foreground their crowns and their jewels, their palettes, and their scientific instruments which have won them fame on earth, their Parliamentary blue-books, and the other outward and visible signs of their earthly professions. Close to this heap of miscellaneous articles an infant, the only one who faces death with pleasure, sits smiling joyfully, and beyond it a mixed crowd, in which figure with many others a ballet girl and a cardinal, a schoolboy, a convict, and a Salvation lass, are divesting themselves not only of their finery but of all their clothes before passing the threshold. It is a picture which will naturally remind everyone of the same artist's work two years ago but is, perhaps, more thoughtfully imagined and less reminiscent of other attempts in the same direction. Below it, for it is above the line, hangs a picture entitled "Hush" (No. 712), by J. H. Lorimer, in which a lady bends over an infant asleep on a bed in a very airy and well-lighted room with a flock of pigeons on the window-sill. Mothers will perhaps think that if she composed the baby in an attitude more conducive to rest she would have a better chance of attaining her object, which is presumably that of prolonging his slumbers.

Of nude figures there do not seem to be quite so many as usual but among them are two graceful, lithe-limbed girls by Mr. H. S. Tuke, A.R.A. (No. 437), who are decidedly attractive. They have none of the flabbiness of the conventional undraped model and are a pleasant change from his usual bathing boys, well painted as these have always been. Perhaps the geological formation of the rocks against which one of them rests herself is left a little doubtful, but Cornish granite has varied tints, and it is upon herself and upon her companion seated on the ground that attention will be centred.

None should leave the Academy without visiting the sculpture, in which such marked advance has been shown in recent years, and those who inspect it will find, in spite of the inadequate accommodation afforded to it, that there is much to admire. The monument to Mr. and Mrs. Gladstone by Sir W. B. Richmond, R.A., of which a model is exhibited, is worthy of high praise as a dignified and impressive work. It is destined to be seen in marble in Hawarden Church, where the inscription will then be more readily legible if it is wrought in the same metal as the other decoration near it, instead of as now in gold.

MEDICINE AND THE LAW.

Claim against an Employer for Attendance upon a Workman.

IN the Bradford county-court an action was recently brought against a manufacturing firm for medical attendance upon a workman, and as the claim was disputed the facts are worth noting by medical practitioners who may be employed in similar circumstances. The plaintiff, Mr. G. H. Oliver, was summoned by telephone by the managing director of the works in question and found the patient, a boy, suffering from a fractured thigh. He suggested that the lad should be removed to the infirmary but the lad protested against being taken there, and, according to the plaintiff's evidence and that of the boy's father, the managing director said that if Mr. Oliver would undertake the case at the boy's home he would be responsible for the charges incurred. Acting on his belief that this was what the managing director in fact meant Mr. Oliver had the boy removed and afterwards attended him at his father's house, but the defendants contended in the county-court that all that had been promised on their behalf was to pay for the original attendance at the works and that the lad's father must bear the expense of everything subsequent to that. The county-court judge was of opinion that there had been a genuine misunderstanding and that neither the medical man nor the employers' managing director had made his meaning as clear as he should have done. He considered, however, that having expressly sent for Mr. Oliver in the first instance the defendants should have made it perfectly clear that they would accept no further liability and he gave judgment for the plaintiff for the amount claimed—£6 17*s.* 6*d.* It has often been pointed out in THE LANCET that when a medical man is summoned to an accident case at a place where workmen are employed he should take care that the question of who is to be liable for his fees should not be left in doubt. In this instance, however, it is not easy to see how Mr. Oliver could have done more to elucidate the matter than he did. He advised the removal of the lad to the infirmary and apperently he also made a direct inquiry as to who would pay if he attended him at his home. The representative of the firm had called him in, so that so far as that occasion was concerned he could not have expected any question to be raised and he must have thought that it was plain to everyone that he would hardly have recommended the infirmary unless the circumstances of the patient had seemed to suggest a charitable institution rather than private attendance. The mistake of the managing director is difficult to account for, but the fact that an action became necessary in order to recover the fees shows how extremely explicit the undertaking to be answerable should be if subsequent dispute is to be avoided.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bath Urban District.—Dealing in his current annual report with the subject of pre-natal mortality Dr. W. H. Symons observes that notwithstanding Section 18 of the Births and Deaths Registration Act, 1874, infants who have been born alive are sometimes buried as having been stillborn without any inquiry as to the cause of death. It seems, too, that the regulations of the Midwives Act to the effect that "in all cases where a registered medical practitioner is not in attendance the midwife shall, as soon as possible after the occurrence of the stillbirth, notify the same to the local supervising authority" are not strictly carried out in Bath, since Dr. Symons has only received eight stillbirth notifications since this Act came into force in April last, and as he thinks that midwives attend more than 50 per cent. of the births he assumes that something like 50 per cent. of the stillbirths would come to their knowledge. Probably this is a fair inference since the midwives will in the main attend the less careful classes. Dr. Symons, from a study of the local records, estimates that about 60 children are annually buried as stillborn in Bath and he thinks that all stillbirths should be registered. Referring to the subject of the sanatorium treatment of pulmonary tuberculosis Dr. Symons states that it is too early to draw conclusions as to the results of the open-air treatment at the Winsley Sanatorium which has been erected for the counties of Gloucestershire, Somersetshire, and Wilts. Eight cases have already occupied the two beds which are maintained at this institution by the corporation of Bath but, like most of the cases so far under treatment, these cases were not very suitable ones, as the number of applications for the beds have been too few to admit of selection.

Borough of Kingston-upon-Thames.—Mr. H. Beale Collins reports that since the attendances at school have been more closely looked after by the school attendance officers the number of cases of scabies has increased, a fact which he attributes to the circumstances that dirtier children have been brought into the schools. He adds that in 30 cases absence from school has been allowed and as some of these cases are absent for months at a time a large number of attendances have been lost. He suggests that if a nurse were appointed to look after these cases they might be cured in a relatively short space of time and in his opinion this same nurse might be used for helping the school teacher to discover cases of the disease in their early stages. 32 physically defective children were found in the schools during 1905 and separate class-rooms are being prepared for them. A special open-air school is suggested for certain cases of pulmonary tuberculosis. As regards vision 121 children were found grossly defective and unless provided with proper glasses they will lose a large portion of their educational facilities.

Bromsgrove Urban District.—Dr. H. Cameron Kidd has been led by a further experience to modify materially the views which he formerly held as regards the advantages of the isolation hospital and he has discovered that these institutions are not always without their drawbacks. In the hospital to which he specially refers there were during 1905 139 patients with only three deaths—a fact which, as he observes, speaks well for the success of the treatment practised. But Dr. Kidd adds that although there has been recently instituted at this hospital an arrangement by which convalescent patients are separated from those in an acute stage there have nevertheless been a number of children who have suffered from such complications as otorrhœa and rhinorrhœa with obstinate soreness of the lips and nostrils. He thinks "that these complications have such obvious connexion with the aggregation of cases in a confined space that I cannot deny that hospital conditions appear to have something to do with their causation." But Dr. Kidd tells us that the wards have not been overcrowded as they used to be in former times when, we infer from his comments, no such complications arose. Among the suggestions made by Dr. Kidd is the provision of the cellular system such as obtains at the Pasteur Institute in Paris, wherein when a patient is admitted, all the other patients are, notwithstanding the cells, inoculated against the disease most recently admitted, that is, of course, if the disease is one—such as diphtheria or small-pox—against which preventive inoculation can be practised. There is, we may add, already one such hospital in England. Dr. Kidd, however, regards such a provision as impracticable and he suggests that there shall be a differentiation among the notified cases, those where there is danger of infection at home being removed to hospital, others being treated in their homes. The diminution of hospital cases which would result would, Dr. Kidd thinks, enable the different blocks to be used for patients in different stages of the same disease. The selection of suitable cases should, he proposes, be left in the hands of the medical officer of health. As regards these observations, we may point out that the incidence of such complications as are here referred to varies materially from year to year, as will be seen by a reference to the annual reports of the Metropolitan Asylums Board, and it is not improbable that these variations also obtain in home-treated cases. But as to this point Dr. Kidd will doubtless have more to tell us next year, as he is probably giving this matter of the comparative incidence of otorrhœa and rhinorrhœa in home and hospital cases his attention. We may also add that where there is a prevalence of such cases in hospital it is always desirable to make sure that any syringes or other instruments used in the treatment of the cases are thoroughly disinfected—i.e., to see that the nurses are carrying out the instructions of the medical officer.

Teignmouth Urban District.—Dr. F. C. H. Piggott is to be congratulated on having at last prevailed upon the sanitary authorities of this district to provide an isolation hospital to which the medical practitioners of the town will not hesitate to send their patients, and commenting upon the absence of such provision in 1905 Dr. Piggott observes that inability to isolate enteric fever "undoubtedly contributed to the issue of the solitary fatal case whose surroundings at home were altogether unfavourable." We gather from Dr. Piggott's report that the Devonshire county council, after holding a local inquiry in 1904 as to the desirability of declaring the whole county a hospital district for the purpose of dealing with pulmonary tuberculosis, came to the conclusion that it would not be justified in making such an order. It is only by making an order such as this that a county council is enabled to erect, or to contribute to the erection of, sanatoriums for tuberculosis.

Borough of Eastbourne.—Dr. W. G. Willoughby, who has been instrumental in bringing about the removal of 94·3 per cent. of the total notified cases of scarlet fever, diphtheria, and enteric fever, has no doubts as to the advantages of an isolation hospital and he observes that "the continued popularity of the sanatorium is very gratifying and is a great factor in the prevention of the spread of infectious disease." He regards the maintenance of a popular infectious diseases hospital as an essential provision, most of all in a health resort. In suggesting the provision of a sanatorium for consumption Dr. Willoughby thinks that admission thereto should be limited to ratepayers of some years' standing, since it would be most inadvisable to attract consumptive patients to Eastbourne.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9435 births and 5080 deaths were registered in the week ending April 28th. The annual rate of mortality in these towns, which had been 17·0, 17·1, and 17·3 per 1000 in the three preceding weeks, declined last week to 16·7; thus the mean rate during the first four weeks of the current quarter was equal to 17·0 in the 76 towns, while in London it was 17·7. The lowest death-rates in the 76 towns during the week were 7·7 in Walsall, 7·9 in Burton-upon-Trent, 8·3 in Wolverhampton, and 8·8 in East Ham; the rates in the other towns ranged upwards to 21·1 in Oldham, 22·3 in Birmingham, 22·8 in Yarmouth and in Hanley, and 23·4 in Liverpool. The 5080 deaths in the 76 towns showed a decline of 170 from the number in the previous week and included 483 which were referred to the principal infectious diseases, against 518 and 519 in the two preceding weeks; of these, 199 resulted from measles, 133 from whooping-cough, 52 from diarrhœa, 46 from diphtheria, 35 from scarlet fever, 18 from "fever" (principally enteric), and not one from small-pox. The deaths from these diseases were equal to an annual rate of 1·6 per 1000 in the 76 towns and to 1·7 in London. No death from any of these infectious diseases was registered last week in Northampton, Ipswich, Norwich, Stockport, Rochdale, and in eight other towns, while they caused the highest death-rates in Bristol, Middlesbrough, Liverpool, Bury, and Yarmouth. The highest death-rates from measles occurred in Bury and Yarmouth, in each of which towns this disease caused five deaths; from whooping-cough in West Bromwich, Warrington, and Wallasey; and from diarrhœa in Oldham. Diphtheria caused three deaths in Walthamstow and scarlet fever three in Tottenham. "Fever" showed no marked fatality in any of the large towns. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals at the end of last week were but six, no new case having been admitted during the week. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday, April 28th, was 2240, showing an increase of 15 upon the declining numbers in recent weeks; 314 new cases were admitted during the week under notice, showing a further increase upon the 270 and 288 cases admitted in the two preceding weeks. The deaths referred in London to pneumonia and other diseases of the respiratory organs, which had been 332, 357, and 399 in the three preceding weeks, declined last week to 361, but exceeded by 72 the corrected average for the corresponding week in the four preceding years, 1902–05. The causes of 50, or rather less than 1 per cent., of the deaths registered during the week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Nottingham, Salford, Leeds, Newcastle-upon-Tyne, and in 50 other large towns, whereas the proportion of uncertified deaths showed a considerable excess in Birmingham, Liverpool, St. Helens, Rochdale, Burnley, and South Shields.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 19·4, 19·1, and 17·6 per 1000 in the three preceding weeks, rose again to 18·4 during the week ending April 28th, and exceeded by 1·7 the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 12·6 and 16·6 in Leith and Perth, to 19·0 in Dundee, 21·4 in Greenock, and 23·4 in Paisley. The 631 deaths in these eight towns included 24 which were referred to whooping-cough, 20 to measles, 11 to diarrhœa, four to diphtheria, three to scarlet fever, and not one either to small-pox or to "fever." In all, 62 deaths resulted from these principal infectious diseases during the week, against 54 and 53 in the two preceding weeks. These 62 deaths were equal to an annual rate of 1·8 per 1000, which exceeded by 0·2 the mean rate during the week from the same diseases in the 76 large English towns. The 24 fatal cases of whooping-cough in the eight towns showed an increase of ten upon the number in the previous week and included 13 in Glasgow, four in Dundee, and two both in Edinburgh and Leith. The 20 deaths from measles exceeded the number in the previous week by five, including 12 in Glasgow and four in Edinburgh. Of the 11 deaths referred to diarrhœa five occurred in Glasgow, three in Greenock, and two in Edinburgh. The four fatal cases of diphtheria included three in Glasgow and one in Paisley; and all the three deaths from scarlet fever were recorded in Edinburgh. The deaths in the eight towns referred to diseases of the respiratory organs, including pneumonia, which had been 170 and 140 in the two previous weeks, further declined last week to 135, but exceeded by 14 the number referred to these diseases in the corresponding week of last year. The causes of 19, or rather more than 3 per cent., of the deaths registered in the eight towns during the week were not certified, the proportion of uncertified deaths in the 76 English towns being rather less than 1 per cent.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 21·1, 23·4, and 28·1 per 1000 in the three preceding weeks, declined to 22·4 during the week ending April 28th. During the first four weeks of the current quarter the death-rate in the city averaged 23·8 per 1000, against 17·7 in London and 19·2 in Edinburgh. The 163 deaths of persons belonging to Dublin registered during the week under notice showed, however, a decline of 41 from the high number in the previous week; they included four which were referred to diarrhœa, two to whooping-cough, two to diphtheria, one each to measles and "fever," and not one either to scarlet fever or small-pox. The ten deaths from these principal infectious diseases were equal to an annual rate of 1·4 per 1000, the rate from these diseases in the same week being 1·7 in London and in Edinburgh. The deaths referred to diarrhœa and diphtheria in Dublin exceeded the numbers in recent weeks. The 163 deaths included 25 of infants under one year of age and 51 of persons aged upwards of 60 years; the deaths of elderly persons showed a marked decline from the number returned in the previous week. Two inquest cases and two deaths from violence were registered; and 66, or more than 40 per cent., of the deaths registered were recorded in public institutions. The causes of five, or more than 3 per cent., of the deaths were not certified either by a registered medical practitioner or by a coroner.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet Surgeon Graham Egerton Kennedy has been placed on the Retired List at his own request (dated April 27th, 1906).

The following appointments are notified:—Fleet Surgeons: J. H. Stenhouse to the *Queen*, on recommissioning; L. Bidwell to the *Aboukir*; and J. L. Thomas to the *President*, for three months' course at West London Hospital. Surgeons: G. M. O. Richards to the *Exmouth* and E. R. L. Thomas to the *Victory*, for R.N. Barracks.

ROYAL ARMY MEDICAL CORPS.

Major T. C. McCulloch joins the London District. Captain R. F. M. Fawcett is granted leave of absence to June 12th next, with permission to travel in Canada. Captain H. E. Howley and Captain J. G. Foster are appointed for duty at Belfast.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Thomas Holt to be Surgeon-Major (dated April 7th, 1906).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Surgeon-Captain Samuel Macfarlane Sloan, Army Medical Reserve of Officers (late Captain, Scottish Command, Glasgow Companies, Royal Army Medical Corps (Volunteers)), to be Captain (dated March 15th, 1906); Supernumerary Lieutenant (Honorary Lieutenant in the Army) G. Lane to be Captain, remaining seconded (dated March 30th, 1906).

VOLUNTEER CORPS.

Rifles: 4th Volunteer Battalion the Royal Fusiliers (City of London Regiment): Supernumerary Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel W. D. Waterhouse resigns his appointment of Brigade-Surgeon-Lieutenant-Colonel (Senior Medical Officer), 2nd London Volunteer Infantry Brigade (dated April 1st, 1906). 4th Volunteer

Battalion the Norfolk Regiment: Surgeon-Captain C. A. O. Owens (Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Norfolk Volunteer Infantry Brigade) to be Major (dated August 1st, 1902). 5th (The Hay Tor) Volunteer Battalion the Devonshire Regiment: Walter Fitzpatrick to be Surgeon-Lieutenant (dated April 28th, 1905). 1st Volunteer Battalion the Leicestershire Regiment: Surgeon-Lieutenant B. Stracey resigns his commission (dated April 28th, 1906). 4th Volunteer Battalion the Cameronians (Scottish Rifles): Alexander Bankier Sloan to be Surgeon-Lieutenant (dated April 28th, 1906). 2nd Volunteer Battalion the Queen's Own (Royal West Kent Regiment): Surgeon-Lieutenant-Colonel H. W. Roberts is granted the honorary rank of Surgeon-Colonel (dated April 23th, 1906). 14th Middlesex (Inns of Court) Volunteer Rifle Corps: Surgeon-Major H. M. Ramsay resigns his commission (dated April 9th, 1906).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Highland Light Infantry Bearer Company: James Alexander Hamilton Aitken to be Lieutenant (dated April 22th, 1906). 2nd London Bearer Company: Captain J. N. Brown is appointed Brigade-Surgeon-Lieutenant-Colonel whilst employed as Senior Medical Officer of the 2nd London Volunteer Infantry Brigade (dated April 1st, 1906). Worcester and Warwick Bearer Company: George William Craig to be Lieutenant (dated April 28th, 1906).

THE VOLUNTEER OFFICERS' DECORATION.

The King has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force, who have been duly recommended for the same under the terms of the Royal Warrant, dated July 25th, 1892:—*London District: Rifle:* 20th Middlesex (Artists') Volunteer Rifle Corps: Surgeon-Captain and Honorary Surgeon-Major Charles Sempill de Segundo. *Northern Command: Rifle:* 4th Volunteer Battalion the Manchester Regiment: Surgeon-Lieutenant (Honorary Major, Volunteers) John Crawhall Nichol. *Scottish Command: Artillery:* 1st Renfrew and Dumbartonshire Royal Garrison Artillery (Volunteers): Surgeon-Lieutenant-Colonel William Robert Sewell. *Southern Command: Artillery:* 1st Devonshire Royal Garrison Artillery (Volunteers): Surgeon-Lieutenant George Clement Searle. *Western Command: Rifle:* 2nd Volunteer Battalion the South Staffordshire Regiment: Surgeon-Major James Scott Wilson. 1st Volunteer Battalion the King's (Shropshire Light Infantry): Surgeon-Major and Honorary Surgeon-Lieutenant-Colonel William Herbert Packer.

THE VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.

The annual dinner of the staff and members of the Volunteer Ambulance School of Instruction will take place at the Trocadero Restaurant on Thursday, May 17th (the anniversary of the relief of Mafeking), at 7.45 P.M. Surgeon-General A. H. Keogh, C.B., Director-General of the Army Medical Department, will be the guest of the school. The following have also accepted invitations to be present: Colonel A. T. Sloggett, C.M.G., R.A.M.C., principal medical officer, London District; Surgeon-Colonel J. Cantlie, London Companies, R.A.M.C. (Vols.), Brigade-Surgeon-Lieutenant-Colonel C. E. Harrison, Brigade of Guards; Major H. C. Thurston, C.M.G., R.A.M.C., War Office; Mr. Mayo Robson, Dr. James Galloway, and Dr. A. Eichholz. During dinner the string band of the 1st Cadet Battalion Royal Fusiliers will perform a selection of music by permission of Lieutenant-Colonel F. Sheffield, commanding.

A MEDICAL COMMISSIONER ATTACKED WITH SLEEPING SICKNESS.

A Reuter's telegram, dated Bukobe (Victoria Nyanza), April 7th, states that it was rumoured at all the points on Lake Victoria that one of the Sleeping Sickness Commissioners sent to Uganda by the Royal Society had contracted the disease whilst engaged in carrying out investigations concerning its ravages at Entebbe, the Government headquarters. The reports are confirmed and it is learned that the Commissioners, Lieutenant Gray, R.A.M.C., and Lieutenant Forbes M. G. Tulloch, R.A.M.C., have left for England. At the end of last month an official telegram was received in London stating that trypanosomes had been found in Lieutenant Tulloch's blood and that as soon as he was well enough he would leave for England. Lieutenant Gray, who was due to leave Uganda on leave of absence at about this time, would, doubtless, accompany Lieutenant Tulloch to England.

DEATHS IN THE SERVICES.

Surgeon-Major Francis Henry Plumptre, I.M.S. (retired), at his residence, Newton Abbot, Devon, on April 17th, aged 78 years. The deceased, who was formerly in the Bombay army, had served in the Persian campaign of 1856–57 and also in the Abyssinian campaign of 1867–68. After his retirement he resided in Newton Abbot and was on the commission of the peace for the county of Devon.

Correspondence.

"Audi alteram partem."

THE COMPULSORY NOTIFICATION OF PULMONARY TUBERCULOSIS.

To the Editors of THE LANCET.

SIRS,—It is an undoubted opprobrium of medical science that so little is done for its progress compared with the work accomplished in other branches of nature-knowledge, and even in surgery, her sister study. The budding physician starts with enthusiastic notions of worlds to conquer and for a time is completely devoted to his new mistress. But as the necessity of making his living impresses itself more and more on his mind, and particularly when what Sir James Paget called in his day the guinea trap appeals to his pockets, he forgets his first fancy.

The cure for this unfortunate condition of matters is the endowment by the State of medical research, which surely with the advance of civilisation must by-and-by become an accomplished fact. Meantime, all honour to those who, Hunter-like, plod on the path of progress, placing a cairn here, making a way there, cheerfully and unweariedly, amidst, alas, too little encouragement. In this connexion I venture to single out two names—those of Jonathan Hutchinson and Byrom Bramwell. Consider the almost Herculean efforts of those two men and the very small recognition of their undenying efforts by the profession at large. That wonderful journal the *Archives of Surgery* has ceased to exist and I fear that *Clinical Studies* does not receive one-tenth part of the support the publication deserves. It costs little and it is worth its weight in gold. My thoughts have taken this turn in connexion with Dr. Bramwell's *Clinical Studies* for April. While giving him unstinted praise for the constant flow of the most interesting kind of matter, he will, I trust, pardon me if I seem to question his great authority and experience. He appeals to medical practitioners to imitate his example and to urge that phthisis should be compulsorily notified by law. I humbly beg to demur to this dictum, and without entering on the wide field of casuistry involved in forcing an individual to place himself voluntarily as a patient in a doctor's hands in a position of *confidence*, to make that doctor reveal what he has got to know in this confidential relation, yet I may be allowed to advance what I take to be some plain objections against the compulsory legal injunction aimed at.

The first is the terrible infliction of labeling any young man or young woman *openly* as a leper to be shunned. Take the kitchenmaid he mentions as the subject of consumption as an example. She was known to be phthisical, I gather, nearly a year before she appeared at the Edinburgh Infirmary a second time. Dr. Bramwell would have some months before certified her as dangerous to others had the law compelled him to do so. But what was the poor girl to do? She must live. She would have been condemned to go out to the streets. It seems to me better that she should die. The public must not shut its eyes to hard facts. With compulsory notification, or rather before we get compulsory notification, there must be the necessary asylums for those so certified.

So much for that objection. The second is that we shall drive every working man and woman *straight* into the hands of the quack, and they are rather too ready to follow that alternative as it is. But supposing an early case does come under the notice of a struggling young doctor and if sanatoriums are to do any real good this is the stage when notification is of the greatest value. Is he, if he can help—that is, if there be any doubts in his mind of the nature of the case—and there are often, very often, many doubts—is he to lose his patient and very likely the patient's connexion by proclaiming to the world, "Here is a leper!" I doubt very much whether we are not asking more than human nature will give. Is it not likely that he will salve his conscience by the chances of a diagnostic mistake and not notify the case at all until, perhaps, it gets so bad that it matters little to him or to his patient whether he does notify or not.

No, Sirs, it will be time enough to enforce notification when the necessary sanatoriums all over the country are ready—and that is a very big job—and not sooner. Long before any kind of compulsory notification was heard of for fevers, there were fever wards and fever hospitals in most populous places. The public has to be *educated*, and this step in the path, as I readily allow, of genuine sanitary progress must come, as everything natural and proper comes, by the laws of evolution and needs much time and much consideration for its complete development.

I am, Sirs, yours faithfully,
W. BRUCE,
April 30th, 1906. Medical Officer of Health of Ross and Cromarty.

THE RECTAL INJECTION OF ANTI-STREPTOCOCCIC SERUM.

To the Editors of THE LANCET.

SIRS,—It was with great interest that I read Dr. Nathan Raw's paper on the value of rectal injections of antistreptococcic serum in ulcerative endocarditis[1] as this week a paper was read by Dr. W. Soltau Fenwick and myself before the Royal Medical and Chirurgical Society on the rectal injection of the same serum in gonorrhœal infections and some cases of purpura hæmorrhagica.[2] The administration of various sera by rectal injection has been practised by us at the London Temperance Hospital during the past six years and two years ago you were good enough to publish a short letter by me on its use. Serum appears to have precisely the same effect when introduced per rectum as if injected subcutaneously, and its action seems equally rapid, while the danger of spreading inflammations and local abscesses at the site of injection is removed and the patient does not look upon the injection in the light of an operation.

I am, Sirs, yours faithfully,
J. PORTER PARKINSON.
Wimpole-street, W., April 28th, 1906.

IN PRAISE OF RUM AND MILK.

To the Editors of THE LANCET.

SIRS,—I was very pleased to read Dr. Francis T. Bond's letter on the above subject. I have prescribed rum and milk in pulmonary complaints with very gratifying results for about 25 years. I have always found good sound rum better assimilated than any other spirit and it seems to combine well with milk, especially separated milk.

I am, Sirs, yours faithfully,
Manchester-square, W., April 28th, 1906. THOMAS DUTTON.

PASTEURISED MILK AND INFANT FEEDING.

To the Editors of THE LANCET.

SIRS,—It may not be known to many of your readers that several of the large dairy companies in London are supplying pasteurised milk to all their customers without any indication that the milk has been so treated. This fact was brought to my knowledge in the following manner: At a children's hospital in London the medical staff decided to use pure fresh milk, unchanged by heat, preservatives, or otherwise, for the in-patients. Extra precautions were taken so as to maintain the purity and freshness of the milk which was to be supplied in sealed and sterilised bottles, and was to be kept on ice. A large dairy company undertook to supply such milk, and did so for about 18 months. At the end of that time it was accidentally discovered that the milk for about 12 months had been pasteurised at the dairy. The company when taxed with this breach of contract, expressed regret but said that it had acted on high medical authority and that pasteurised milk was really safer for infants than milk not so treated. Into this question the medical staff did not enter but proceeded to secure untreated milk from another source. This action on the part of the dairy companies is one of considerable public importance. In the first place, the pasteurising of the milk is not undertaken by them for the benefit of the infant population but for the purpose of protecting themselves from spreading typhoid fever or other disease through contaminated milk, with subsequent legal proceedings and heavy damages. They may or they may not be justified in taking this precaution, but their customers are at least entitled to know the fact that the milk has been pasteurised. What is cows' milk? This is a difficult question to answer, but it is certainly inadvisable to allow the dairy companies to plead in the future "the custom of the trade" in selling pasteurised milk when fresh cows' milk is ordered. If pasteurised milk is to continue to be sold it ought to be labelled as such, just as condensed and "humanised" milks are.

Again, the health of the children may be seriously affected by this action of the dairy companies. At present, and largely owing to medical teaching, it is the custom in many households to boil the milk on delivery. If the milk is first pasteurised by the seller and then boiled by the purchaser, it will be a poor, devitalised sort of food which eventually reaches the infant, and anæmia and scurvy may be expected to follow. These are the results which one would anticipate on theoretical grounds, and practical evidence is forthcoming as follows: Dr. W. S. Colman[1] relates that a short time ago there was an epidemic of infantile scurvy among children in Berlin supplied with pasteurised milk from an institution, but it was found to be confined to children whose parents, as an additional precaution, boiled the pasteurised milk for some time, after it was delivered to the house. More recently Dr. J. A. Coutts[2] has recorded three cases of scurvy at the East London Hospital for which the patients were *ordered* fresh cows' milk and were further treated in the usual way with raw meat-juice, scraped potato, and lemon-juice. In none of the cases did the usual speedy resolution of the subperiosteal clot take place. "That three consecutive cases of scurvy should take this extraordinary course led to an inquiry and it was discovered that for several months the dairy company to the hospital had been supplying pasteurised instead of fresh milk, without the hospital authorities being adequately informed of the change. On the substitution of fresh for pasteurised milk each infant began to improve." These facts speak for themselves and would seem to justify the anticipation that injury to the health of the children and aggravation of their diseases will result if this action of the dairy companies is allowed to continue. More especially will the danger be present if the public and the profession are kept in ignorance of the fact that the milk is being pasteurised.

I am, Sirs, yours faithfully,
April 30th, 1906. G. A. SUTHERLAND.

100 CONSECUTIVE CASES OF MEASLES WITHOUT CHRONIC MIDDLE-EAR DISEASE.

To the Editors of THE LANCET.

SIRS,—Within the last 12 months I kept notes of the first 100 cases of measles which I attended during an epidemic and amongst this number I had not a single case of chronic middle-ear disease. At the most I had one or two cases of earache which soon got well without discharge of any kind. Although I have no actual figures to prove my contention I feel sure that 20 years ago it would not have been possible to attend 100 consecutive cases of measles without at the same time having several cases of "running ears." When I began practice 14 years ago it was common to find on asking the cause of deafness or of purulent ear disease to be told in an off-hand manner, as if it was a matter of course, that the mischief had existed since the patient had had measles. Within recent years I have found that measles is not so often given as a cause of this troublesome affection but in order to prove or disprove the correctness of my impressions I made the observations now recorded. That the epidemic was not particularly mild is shown by the facts as follows. The deaths numbered four, two being due to broncho-pneumonia; one was helped by the teething process and one by whooping-cough, and all occurred in children under 18 months. Other notable points are: two out of the 100 were adults, and they had not had the disease before, six had had measles previously, and one or two had had more than one attack. "Pronounced"

[2] West London Medical Journal, April, 1906, p. 82.

broncho pneumonia was the commonest complication. Three had well-marked laryngitis—one of these began with laryngitis as the first symptom of the disease and one had subsequent laryngeal paralysis (a girl, aged six years). The majority of the patients were under five years of age and belonged to the working-class section of the community.

One may well ask, what is the reason of this great improvement in results as regards the middle ear? I believe it is due (1) to a rise in the standard of general cleanliness amongst the great body of the people; and (2) to a better appreciation of the laws of hygiene as therapeutic agents amongst the members of the medical profession These laws I have tried to interpret and to practise as follows: 1. To keep the rooms comfortably cool and as fresh as possible, as opposed to the sweltering heat of former days. 2. By attention to the patient's skin; frequent sponging down. Changing the patient's dress as often as necessary. Wrapping the child in a sheet with a blanket outside instead of the sweat-laden blanket in which the poor patient used to be invariably wrapped. 3. By allowing the patient plenty of cold water, soda water, lemonade, or other cool fluid of a similar kind in the early days of the disease. The food to be diluted milk. Not forcing solid food against the wish of the patient. By adopting this line the pharynx and naso pharynx are kept sweet and hence the chances of mischief extending along the Eustachian tube to the middle ear are greatly reduced. Tact is necessary often to get these orders carried out, especially if there is a grandmother in the question. Medically I give one-twentieth of a grain of tartrated antimony along with half a fluid drachm of solution of ammonia and the same of simple syrup three or four times a day to still further keep the skin and kidneys active. When the cough is particularly troublesome I add to the foregoing one or two minims of tincture of opium according to age. Ordinarily I leave the cough to take care of itself.

I do not believe measles has lost its virulence and if patients, generally speaking, were placed under the foul conditions of former days chronic affections of the middle ear would be as frequently met with as of yore.

I am, Sirs, yours faithfully,
Leeds, April 26th, 1906. GORDON SHARP.

THE BRITISH DENTAL ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—Will you kindly permit me through your columns to apply for the loan of specimens—microscopical sections, photographs, or skiagrams—of odontomes and such tumours as may be included when this term is used in its widest sense? The loan of specimens from so many collections, both public and private, has been promised us that we are endeavouring to make this collection as complete as possible, and by the aid of medical men who have been fortunate enough to obtain specimens of these tumours we hope we may add to our museum. The museum is to be held in connexion with the annual meeting of the British Dental Association which takes place in London at the Examination Hall of the Royal College of Surgeons on May 17th, 18th, and 19th next. Will those who possess specimens be good enough to communicate with me at the address given below?

I am, Sirs, yours faithfully,
W. W. JAMES,
Honorary Secretary, Museum Committee.
12, Wimpole-street, W., April 30th, 1906.

MEDICAL AND DENTAL DEFENCE UNION OF SCOTLAND, LIMITED: PURVES v. CARSWELL AND GILCHRIST.

To the Editors of THE LANCET.

SIRS,—In sending the annual report of the union to non-members a note was inclosed stating that the defence in the above actions was conducted by this union. In view of the vital importance of the issue to the medical profession generally the council, after due consideration, decided to give the defenders the use of the name and organisation of the union, but unfortunately a misconception seems to have arisen as regards the liability of this union for the costs. Mr. John Carswell and Dr. Marion Gilchrist not being members of the union when the matter occurred out of which the action arose, were therefore excluded from the privileges of membership in respect of that matter and have to pay the entire costs of the action, amounting to fully £900. As a misinterpretation of the note accompanying the report is apparently checking the flow of subscriptions to the Carswell and Gilchrist Fund the union desires by publishing this explanation to second the efforts of the special committee in soliciting contributions, which should be sent to Dr. W. G. Dun, 15, Royal crescent, Glasgow, W.

We are, Sirs, yours faithfully,
ROBERT W. FORREST, M.D. Glasg., Chairman.
WILLIAM YOUNG, Secretary.
108, West George-street, Glasgow, April, 1906.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The University.

THE summer term commenced on April 23rd and the students seem to have settled down to steady hard work at once. This is perhaps due to the fact that the summer term is short and that many of the University examinations take place during the latter half of June. The Principal, Sir Oliver Lodge, has returned after his long rest. His holiday appears to have had very beneficial effects, for he looks strong and well. It is pleasant to see his big form and cheery, purposeful face about the place again, for he seems to diffuse encouragement and energy into everything which is under his charge.—It is becoming the custom in the Medical School for one or more members of the staff to deliver during this session short courses of lectures to which practitioners in the city and surrounding district and the students of the University are invited. The lectures are delivered on Thursday afternoons at 4 P.M. in the medical theatre, as has been already announced in THE LANCET. They were commenced on April 26th by Professor J. T. J. Morrison who is delivering a course of three lectures on the Legal and Social Relations of English Medicine, Past and Present, and they will be continued by Professor Robert Saundby who, on June 7th, commences a course of three lectures on Medical Ethics. On May 17th and May 24th Dr. O. E. Purslow, who is Ingleby lecturer for the year, will lecture on the Management of a case of Labour. The Ingleby lectures are also open both to practitioners and students. Professor Morrison's lectures have been extremely interesting, for by examining old records and ancient books he has been able to place before his audience in a most attractive manner an account of the history of the practice of medicine and surgery in this country, tracing it from its first beginnings in the hands of the priesthood to its transference to the laity and showing how gradually, at various times, the practitioners have attempted to consolidate their powers and privileges. Those of us who have but little time for looking into old records are deeply grateful to Professor Morrison for the glimpse he has given us of many past events associated with the history of the growth of our profession.—The new pathological department was not in a sufficiently advanced state to be opened at the beginning of the session and I understand that there will be no formal opening ceremony. Work will probably be commenced in the new buildings in about three weeks or a month. In future the pathological department will do much more work for the health department of the city than it has hitherto undertaken. This increase of work will necessitate the appointment of an additional assistant who will have to devote himself chiefly to public health work.

The Women's Hospital.

There is much cause for congratulation and a little for regret in association with the annual report of the Women's Hospital. The statistics for the year show that the total number of cases treated was 17,656, or 993 less than the previous year, the diminution in number being accounted for by the fact that the out-patient department was closed last August for alterations and additions. The number of in-patients treated was 492, an increase of 13 on the previous year. The most satisfactory parts of the report are those dealing with the new hospital which was opened in September last and the account of the mortality-rate after abdominal section. The new buildings and equipment have added greatly to the efficiency of the arrangements of the hospital and the death-rate in 275 cases of abdominal section was only 2·1 per cent. In the previous year the death-rate was 2·3 per cent., and the average rate since the founding of the hospital in 1904 is 5·7 per cent. The rate for the past year compares very well with that of other similar institutions. The main cause for regret in the report was the statement regarding finances. The new hospital was only open for three months during 1905 and the ordinary income and expenditure account showed an adverse balance of £1500. It follows, therefore, either that some enlarged source of annual income must be attained or that the work of the hospital must be crippled. The subscription list only amounts to £1000, a strangely small amount from a city with so many wealthy inhabitants to such an important hospital, and it is certain that the annual income must be increased by £1000 if the work is to be continued on its present scale. The hospital is to receive a legacy of £308 under the will of the late Mrs. Hannah Pullom, who left the residue of her property to the institution.

Tree Planting in the Black Country.

The Midland Reafforesting Association has been at work for three years and the results it has attained have been most encouraging. Its members three years ago were 50 in number; they are now 250 and many people who scoffed at the idea of success are becoming convinced of their error. Through the agency of the association 70,630 trees have been planted on 43 acres of land. Since last year 37 acres have been planted and of these 34 acres were land at Moorcroft near Moxley, belonging to the South Staffordshire Joint Small-pox Hospital Board. The plantation thus established lies to the north of the Great Western Railway and it will replace a black patch, which was in full view of travellers, by a verdant grove of trees, for the trees, which were examined a short time ago, seem to be establishing themselves well. The corporation of Wednesbury needs a park extension and in order to provide it the association has planted 2000 trees on two acres of pit-waste at King's Hill. No special soil is used for planting purposes, for it is found that a mixture of the burnt ash of the mounds with the blue clay, or "church," which is found upon them makes a satisfactory soil. The chief difficulty, however, in establishing plantations on the bare mounds of ash and waste is not the soil but the impurity of the atmosphere. There is reason to believe, however, that the atmosphere is becoming less impure and it is hoped that in future unnecessary emissions from forges and furnaces will be abated. Smoke alone is not so great an enemy and Dudley Castle Hill is now thickly covered with trees though furnaces abound in the neighbourhood. In addition to other work the association has established four nurseries and has stocked them with trees likely to be most useful. Now that it has demonstrated that success can be obtained it is going to try new varieties of trees which have not hitherto been grown in the Black Country. Last September the association asked for gifts of willow cuttings and His Majesty the King was among the first to respond with an order for 20,000 to be sent from Windsor. Some of those received were sent to the plantations and others were placed in the nurseries. At the present moment the association has in stock for next season 23,918 trees and 35,500 cuttings. Much has been done in the past three years and probably more will be done in the future, for people are realising that the association is doing good work. Therefore it will meet with more help and encouragement. It will have the full sympathy of the medical profession, for it is not only making the surroundings of the people more beautiful and so increasing their happiness and ideals, but it is also improving the air and the land and so giving the inhabitants better chances of health and strength.

Birth- and Death-rates.

Birmingham has established another lowest quarterly birth-rate. the birth-rate for the first quarter of the year being 30·6, which is the lowest on record for that quarter. It is higher, however, than the rate in the fourth quarter of last year, 26·9, which was also a record for its quarter. The rate varies in different wards from 19·1 to 40 per 1000. The death-rate for the first quarter, 17·9 per 1000, is slightly higher than that for the corresponding quarter of the preceding year, but still it is good for its quarter. The medical officer of health of Worcester points out in his annual report that the general death-rate of that city declines each year, but the infantile death-rate shows no improvement, indeed, during the past year it was 156 per 1000, which is slightly higher than the average rate for the previous ten years. This is the more remarkable since there have been no marked epidemics of infectious disease during the year. It is evident that the people in Worcester need instruction in the care of their children. Bilston has been suffering from measles and whooping-cough, with the result that the medical officer had to report that during March there were 69 deaths, or 32 more than in the corresponding month of the previous year. Of the 69, who died only 20 were over five years of age.

May 1st.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

The Laying of the Foundation-stone of the Liverpool Country Hospital for Chronic Diseases of Children.

THE foundation-stone of the Country Hospital for Children, which is being built at Heswall, was laid on April 21st by Mr. Andrew Gibson. When the entire scheme is carried through the hospital will provide accommodation for 200 beds and its total cost will be £60,000. The committee is confining its initial effort to the provision of only 100 beds. During the seven years that the institution has occupied temporary quarters at the convalescent home, West Kirby, experience of great importance to the work of treating children suffering from chronic diseases has been gained. The value of uninterrupted treatment in the fresh air of the country has been amply demonstrated, and the good results which have attended the work at West Kirby, where its scope has been necessarily restricted by the fact that only 25 beds were available, encourage the hope of a much larger sphere of usefulness in the future arrangements for the treatment of the children. The site for the new hospital, comprising ten acres, is on the side of Heswall Hill. When the complete scheme is carried into effect the buildings will stand in the form of the letter H, the ward wings being connected by the central block. At present only the central block, in which temporary ward accommodation can be found for 100 beds until the ward blocks themselves are erected, is being undertaken. This part of the scheme will cost £25,000 in addition to £15,000 for furnishing, general equipment, and liabilities in connexion with the building. The ceremony was witnessed by a large and important gathering presided over by Colonel Montgomery, the chairman of the hospital. Messages of apology for absence had been received from the Bishop of Liverpool, the Bishop of Chester, Sir Edward Russell, and others.

Opening of the Fazakerley City Hospital.

Another of the big enterprises of the Liverpool city council —the City Hospital, Fazakerley—was formally opened on April 25th by Mr. John Utting, the chairman of the port sanitary and hospitals committee, in the presence of a large gathering of the public representatives and officials of the city. The proceedings were presided over by the Lord Mayor. The hospital, which consists of a central administrative block, nurses' home, and a number of one-storey wards and isolation pavilions, stands on an area of 35 acres, the surrounding country being fine and open to the exhilarating north-west breezes from the direction of the sea. It was planned by Mr. Shelmerdine, the city architect and surveyor, with the valuable assistance of Dr. E. W. Hope, the medical officer of health; the buildings have been erected by Morrison and Sons, of Wavertree, at a cost of £121,475, to which must be added a large sum for equipment and the cost (£39,915) of the 118 acres of land purchased in 1898. The south section of the institution, which was completed in 1901, provides 160 beds for the treatment of small-pox, and the additional buildings opened on April 25th give accommodation for 350 beds for dealing with other infectious diseases. Sir James Crichton-Browne, in seconding a vote of thanks to the Lord Mayor for presiding, said that they had in this country a duplex system of sanitation, both unified and both parts of which were of extreme importance. In Liverpool they had the port sanitary authority presided over by Mr. John Utting, which might be called the blue-water school of public health officials, who were engaged in defending and safeguarding our shores against foreign invasion. They had also the land forces, the urban and rural sanitary authorities, who were engaged in dealing with those foreign foes in the form of diseases that had obtained a foothold in our land and such rebellious diseases as had sprung up amongst us. He thought we might have as complete confidence in our blue-water sanitary officials as we had in our navy. It was certain that in this country we should have from time to time raids of foreign diseases, but, thanks to the precautions taken at that and similar hospitals, we should never again have those terrible invasions which we have had to deplore in the past. Mr. John Utting was presented with a key of solid gold bearing the Liverpool coat of arms in true heraldic colours, also the staff of Æsculapius, together with a view of the hospital, all being beautifully enamelled, the wards of the key forming the recipient's initials, the reverse side being suitably inscribed.

St. Helens Hospital: Annual Report.

The most interesting feature in connexion with the statement made by the treasurer at the recent meeting of the subscribers to the hospital was the fact of the support given to the charity by the workmen of the district. Out of 707 patients admitted during the year 563 were penny-a-week subscribers. The total subscriptions from this source during the year were £2478 odd, the total income being £3804 10*s.* 1*d.* and the expenditure £3795 12*s.* 8*d.*

May 1st.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

General Council of the University of Edinburgh.

THE statutory half-yearly meeting of this body was held on Wednesday, May 2nd. Various matters came up for consideration, the most important being the proposed alterations in the medical curriculum and a proposal that steps should be taken to have autonomy granted to the several Scottish Universities. (The proposals are given in detail at p. 1266.)

Post-Graduate Course in Edinburgh.

The Edinburgh Medical School has once more aroused itself to the fact that in an important centre such as Edinburgh it is desirable to have opportunities for post-graduate instruction. A laudable beginning with such a scheme was made a number of years ago but the founders, already weighted with the burden of under-graduate teaching, gradually withdrew from it. The idea has again taken practical form and it is proposed to begin a short course in September next.

The Glasgow University Club.

The annual summer dinner of the Glasgow University Club, London, has been fixed for Friday, May 25th. It will be held at the Trocadéro and the chair will be occupied by Sir Thomas McCall Anderson, head of the medical faculty of the University and a member of the General Medical Council, which will be holding its sittings in London during the same week.

Infantile Mortality in Barrhead.

For some time the high death-rate among infants in Barrhead has been engaging the attention of the town council. The method was tried of distributing circulars containing information regarding the care of infants, but the results accomplished in this way have not been satisfactory and more effective measures are being considered. Dr. R. Corbett, the medical officer of health of the burgh, in the course of an interesting report on the subject states that the increase of infantile deaths among the poorer classes is due in great part to carelessness and ignorance in feeding and protecting the children. As he finds it impossible to come into constant touch with these parents, he recommends, in the interests of public health, that a qualified nurse should be appointed to assist in the way both of advice and of practical household demonstrations in the proper methods of feeding, cleaning, and clothing young children. As it is imperative that such a nurse should be able to offer her services as soon as possible after a baby is born it is advised that a small sum, say 1*s.*, should be given to the first person who reports a birth to the nurse. As a number of births in Barrhead occur without the attendance of a medical practitioner it is further suggested that the nurse should be qualified to attend ordinary midwifery cases and that she attend women during their confinement if they desire her services. The town council has agreed to adopt this proposal of the medical officer and the experiment is to be tried for one year.

Sanitary Condition of Lewis.

The deplorable sanitary condition of Lewis has again been brought before the public by the publication of the annual report of Dr. W. Bruce, medical officer of health of Ross and Cromarty. In referring to Lewis, he says that the state of matters can only be considered as desperate. Here we have to deal with a poverty-stricken people living in conditions 100 years or more behind modern civilised ideas of mere existence. The proprietor of the island, though willing, cannot build some thousands of clean and comfortable cottages from his own purse, already drained to the utmost by poor- and school-rates. It has been said that the local sanitary authority should do its duty and compel these poor people to conform to twentieth century notions as to the propriety of dividing the human and bovine elements in their household accommodation. Recently Dr. Bruce visited one of the villages with this point in view, only to find that the separation meant next to no sanitary improvement and that it was impossible to drain the village without moving almost every house away from the muddled hollow in which it lies, rebuilding it on the higher ground adjacent, and finally digging a deep and expensive ditch through the rock to carry off obnoxious liquid matters.

May 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Outbreak of Scarlet Fever in Kildare.

AN outbreak of scarlet fever which originated in the military barracks at Kildare has already caused one death. There are 20 cases in the barracks and 10 in the town which are very serious. Every precaution is being taken by the military authorities and by the local medical officer of health. All dealers' passes from Kildare to the Curragh Camp have been stopped. On April 30th the military medical inspector of the Dublin and Belfast districts with Major Hennessy, R.A.M.C., and Dr. L. F. Rowan visited the barracks in order to investigate the cause of the outbreak. The Naas union fever hospital, which is the nearest to Kildare, is 14 miles from the town, so that the difficulty of removing patients is considerable. In fact, Dr. Rowan has found it necessary to request the military authorities to set apart a ward in the Curragh Camp fever hospital for the use of civilian cases in the event of the epidemic spreading further.

Health of Belfast.

The papers are still discussing the high death-rate in Belfast from tuberculosis and other causes. The following table, embracing a period of three months, shows the unenviable position which Belfast holds at the present time in comparison with the rest of the kingdom as to its high death-rate:—

Week ending—	Average of the great towns.	Belfast rate.	Belfast excess
Feb. 3rd	15·5	20	4·5
" 10th	15·5	21	5·5
" 17th	17·2	26	8·8
" 24th	17·3	25	7·7
March 3rd .	17·4	24	6·6

Average . .	16·6	24	7·4

Belfast and County Antrim Branch of the Royal Medical Benevolent Fund Society of Ireland.

At the annual meeting of the above society held in the Medical Institute, Belfast, on April 27th, Dr. J. Nelson, the President, being in the chair, it was reported that the amount received from all sources was £153 2*s.* 6*d.*, made up as follows: 127 Belfast members, 29 country members, and 14 friends and sympathisers not belonging to the medical profession. Deducting expenses the total amount was

£122 18s. 2d. For some reason there has been a falling off of £22 1s. 11d. The total sum paid in grants was £145, a sum in excess of the local contributions to the Fund. Only 127 out of 204 members of the medical profession in Belfast subscribe and only 29 medical men in the country contribute. Professor J. A. Lindsay was elected president for the ensuing year. An effort is to be made to interest the members of the profession in the society.

The Darnell Case.

At a joint meeting of the Ulster branch of the British Medical Association and of the Ulster Medical Society held recently it was decided to start a fund to assist Mr. C. K. Darnell in defraying his expenses at the recent trial.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Paratuberculosis.

AT a meeting of the Academy of Medicine held on April 10th M. Poncet returned to a theory of which he has made himself the champion and which is as follows. He considers that the bacillus tuberculosis, whether of itself or by means of the toxins which it secretes, is capable of producing in the organism various lesions of an extremely diverse character, in the production of which the action of the bacillus has not been up to the present suspected. The field of action of tuberculosis, which is already only too wide, is thus found to be much increased but at the same time certain lesions the origin of which is difficult to account for can be explained satisfactorily on this hypothesis. M. Poncet, for instance, considers that there is a tuberculous rheumatism without any tuberculous bacilli being visible locally but that the local lesions are the result of an intoxication by the bacillary toxins. There are certain tumours of the breast and of the thyroid gland—namely, the adenomata—which surgeons have great difficulty in distinguishing from cancer. M. Poncet considers that these adenomata have all the character of inflamed reactive tumours. They possess no definite microbial forms nor very often any bacillus of any kind, but having studied the hereditary history of patients affected with adenomata, and by comparing their clinical forms, M. Poncet considers that they are of a tuberculous nature. M. Labbé asked M. Poncet for more definite proofs of his argument and remarked that tuberculous lesions which were free from bacilli could be inoculated into animals, such as the rice-grain bodies found in cases of synovitis. M. Poncet answered that these lesions were not tuberculous properly so called but inflammatory, although their structure indicated that the primary cause of the inflammation was tuberculous. M. Fournier said that M. Poncet's idea was plausible and all the more in that it presented an analogy to the idea which he (M. Fournier) had often put forward on the subject of syphilis. Thus, the syphilitic virus does not produce anything but syphilis, but under certain conditions it produces lesions of which the syphilitic character is by no means evident, lesions which resisted treatment by mercury and the iodides but which cannot be produced without the intervention in the beginning of syphilis. Such lesions, for instance, are tabes and general paralysis, and in these conditions we have the right to talk of parasyphilis. Similarly, in certain maladies of the skin, such as lupus erythematosus and the tuberculides, no bacillus of tuberculosis is found in the majority of cases but yet they are tuberculous in origin. There is no reason then why we should not admit the possibility of a paratuberculosis.

April 30th.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

The German Congress of Orthopædic Surgery.

THE German orthopædists who formerly were members of, and took part in, the Congresses of the German Surgical Society have since 1902 combined to form a separate association to which they have given the name of the German Society for Orthopædic Surgery. They had found that in comparison with the other branches of surgery orthopædic surgery did not receive the consideration to which they believed it to be entitled. Moreover, the number of papers read before the German Surgical Congress was so great that there was no opportunity for a discussion after many of them, and especially after those dealing with orthopædic surgery. The orthopædists therefore hold a special meeting of their own of only one day's duration on the day before the opening of the German Surgical Congress in order to allow members to take part in both Congresses. The Fifth Congress of the Society for Orthopædic Surgery was accordingly held in Berlin on April 3rd, Professor Lorenz (Vienna) being in the chair.—Professor Schulthess (Zürich) read a paper on a Peculiar Form of Scoliosis which occurred in young children having a tendency to rickets and was encouraged by the children lying in their cradles in unnatural positions. Mothers ought, therefore, he said, to pay great attention to the positions which children assumed in the cradle.—Dr. Finck (Charkov) read a paper on the Gradual Reduction of the Deformity produced by Pott's Disease. In contradistinction to the forcible reduction practised by Calot the principal feature of this method was that the patients must remain at perfect rest for several months or even a year wearing a plaster-of-Paris apparatus padded with cotton wool, by which continuous pressure is maintained on the deformed part. After several months they are allowed to walk by the aid of supports which reach as high as the occiput and the angle of the jaw. They begin by getting up for half an hour, a period which is by degrees extended to six hours, and in the intervals they are again placed in the plaster-of-Paris apparatus.—Dr. Spitzy (Graz) recommended the transplantation of nerves in cases of paralysis. He showed a boy, aged 12 years, who had suffered from paralysis of the radial nerve and had been successfully treated by uniting fibres of the median with the paralysed radial nerve.—Dr. Cramer (Cologne) described an operation for restoring the mobility of an ankylosed elbow.—Dr. Withek (Graz) read a paper on Dislocation of the Hip-joint. He said that in old cases of dislocation extension by weights, even as heavy as 50 kilogrammes, must be used.—Professor Lorenz said that reduction of these dislocations must not be made at too advanced an age because ankylosis might easily develop.—Dr. Heusner (Barmen) remarked that extension which was too forcible tended to produce loosening of the knee-joint.—Other papers read before the Congress dealt with trophoneurotic diseases of the joints occurring after poliomyelitis, habitual dislocation of the patella, the mechanical treatment of dislocation of the hip-joint, the treatment of club-foot, and the treatment of varicose veins.

Statistics of Suicide.

According to the statistics published by the Imperial Statistical Office, the number of suicides has slightly decreased, being 12,468 in 1904 as compared with 12,730 in 1903. The proportion of suicides per 100,000 of the population was 21·0 in 1904, 21·7 in 1903, 21·4 in 1902, and 20·8 in 1901. Arranged according to sex, in 1904 there were 9704 and in 1903 there were 10,017 suicides among males; while in 1904 there were 2764 and in 1903 there were 2713 suicides among females, so that the decrease occurred only among the males. With regard to the local distribution of suicides the report states that the lowest number was reached in the Prussian provinces of Posen, Hohenzollern, and Westphalia, being 9·9, 10·3, and 11·0 per 100,000 respectively. The highest numbers were registered in Saxe Coburg and Saxe Altenburg, being 41·8 and 41·5 per 100,000 respectively. In Hamburg 37·8 and in Berlin 31·0 suicides per 100,000 were registered.

April 30th.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Sixth International Congress of Criminal Anthropology.

FROM Portugal to Piedmont, from Lisbon to Turin, is a trip delightful at all times, whether by sea or land, but particularly so when undertaken by the professional man who, satiated from the abundant and varied *menu* of the Fifteenth International Congress of Medicine, passes on to the piquant bill of fare provided by the Sixth International Congress of Criminal Anthropology. I have already indicated some of the attractions of this latter symposium and will only add on this, the morning of its inauguration, that both in its *personnel* and in its programme it promises to be yet more successful than the last and best of its predecessors. Besides M. Magnaud, the *bon juge*, there will intervene three ex-Ministers of State, M. Lejeune, representing the "newest of the sciences" in Belgium; Van Hamel, its able pioneer in Holland, especially in the "care and cure of minor delinquents"; and M. Vucetig, already known for good work as a criminal anthropologist in Servia. Interest, dramatic as well as scientific, cannot fail to attend the contributions to the agenda paper on "The Female Assassins in Russia," Mde. Tarnowski and Mde. Rublinovich being the authors; while M. Drill Dmitri, of the same nationality, will discourse on the Effects of Seclusion in the Island of Sakhalin on its Criminal Population. M. Hamon, conductor of *L'Humanité*, and M. Habanel, of judicial fame, will treat of the Mental Rehabilitation of Weaklings of Tender Years; and in the investigation of crime Dr. Ottolenghi and Signor Guasti (the highly efficient "Ispettore di Pubblica Sicurezza") will give their experiences of the anthropometric system, supplemented by a paper from Dr. Reuss of Geneva, entitled "L'Applicazione della Fotografia alla Ricerca dei Delinquenti." From the sections in which these and other cognate themes will be discussed by experts the auditor can find recreation or distraction in the "Esposizione" held as an adjunct to the Congress in the "Istituto di Medicina Legale al Valentino." Among the objects on view will be a beautifully arranged and clearly described assortment of the brains and the skulls of executed criminals, contributed by Professor Haberda of Vienna; an equally well-classified series of skeletons and masks of notorious Italian "giustiziati" sent by Professor Tenchini of Parma; and a collection of the favourite lethal weapons of the Neapolitan Camorra with their characteristic inscriptions, the contribution of Professor Frigerio. Most effective, however, from the "gruesome" standpoint is the famous Virgin of Nürnberg, a statue of a woman made of iron and hollow inside, which opens on its hinges, like a cabinet, to receive the victim, on whom it closes immediately, piercing with its inner apparatus of sharp spikes his eyes, his breast, and his abdomen till he dies in excruciating agony. Too often put in practice, this instrument of "justice" could never have been "deserved" but by the human fiend who devised it. As already stated,[1] the proceedings will open with a testimonial and address to Professor Cesare Lombroso, the initiator and indefatigable promoter of "criminal anthropology," whose career, honourable in itself, illustrates the qualities and "the defects" of the said qualities which go to make the "pioneer" Beginning life as a humble practitioner of medicine in which he had graduated with distinction young Lombroso's first academic post was that of lecturer on medico-psychology in the University of Pavia, in the wards of whose asylum he was impressed with the close connexion between lunacy and defective nutrition, most of the inmates having suffered or but partially recovered from that scourge of the Alta Italia, "pellagra." Tracing this disease to the badly grown maize, which was the staple food of the people, he gave himself no rest till, in spite of much opposition, not to say obloquy, he had wrung from the authorities, agricultural and other, a series of prophylactic measures which have since reduced the numbers of the "pellagrosi" and the intensity of their pathognomonic signs. Following up his researches into the interdependence of malnutrition and mental deficiency he received great encouragement from his fellow worker in the same direction, Paul Broca, and for several years concentrated his studies on the causation, or rather on the "conditions precedent," of epilepsy in all its stages and throughout all its ramifications. To these studies we owe his widely diffused, if not widely accepted, theories on the association of the "epileptoid cachexia" with abnormal developments, sometimes appearing in so-called "genius" and much oftener in eccentricity of character and in crime. Comparative craniology further supplied him with what he considered as confirmatory evidence and the whole culminated in his "Uomo Delinquente," the work of 15 years of observation and research. Then followed his "Uomo di Genio," translated into six European languages, the conclusions of which found many adherents not only in Italy but in Russia and in North and South America, while accepted only provisionally in Germany and Austria when not absolutely rejected. The net result, however, of his teaching, or, I should say, his propaganda, has not been without its salutary side in his native Italy, where the conditions, physical and moral, which antagonise healthy and normal development, particularly among the poor, have prevailed long enough to produce a population in which crime multiplies itself out of all proportion to its manifestations in other continental countries. It is in recognition of the good he has done directly by individual work, indirectly by example and influence continued over 30 years, that the testimonial has been accorded him to-day—a testimonial to which all the leading anthropologists interested in the phenomena of crime have appended their signatures—at this, the Sixth International Congress of the science which he is known to have fostered as well as founded.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Eyesight of School Children.

AT a recent meeting of directors of elementary schools Professor Schnabel, the chief ophthalmologist of the first clinic for ophthalmology, read a paper on Myopia in School Children. He said that myopia was very frequent amongst the rising generation. He had examined the eyes of more than 4000 children of both sexes at ages between six and 14 years and 1450 eyes of youths and girls at ages between 14 and 19 years. He was decidedly of opinion that school work was not responsible for myopia of comparatively high degree, such as five, ten, or 15 dioptres. As a rule, such excessive nearsightedness was congenital—mostly produced by staphyloma posticum or excessive curvature of the lens and its capsule. The percentage of myopia at the ages from six to 14 years was nearly constant, and in the more advanced schools the percentage was somewhat raised but only very little. The most deleterious factor of myopia amongst young people consisted partly in hereditary influences and partly in the performance of fine work, such as sewing, etching, and watchmaking. It very rarely, if ever, happened that either severe mental strain (such as that of preparation for examinations) or excessive reading in a good light was responsible for loss of elasticity of the lens capsule. Reading in an unsuitable light was apt to endanger the vision without causing myopia. Hypermetropia was also found amongst a fair percentage of children. This fact was especially important, as most of these children, unless examined by an ophthalmologist, were supposed to be suffering from myopia because they were in the habit of bringing their eyes very near the book which they were reading or the paper on which they were writing. They generally used only one eye because they had to visualise the letters without accommodation. Such children very often suffered from headache if their hypermetropia was not corrected by proper glasses and were likely to be far behind the average standard of knowledge of their class-fellows on account of their liability to myasthenia musculi recti interni. Great attention should therefore be paid to the eyes of children, both as regards school work and also as regards their home occupations.

The Relation of Nasal Disease to the Functions of the Female Genital Organs.

Several interesting experiments devised for the purpose of elucidating the relations existing between the nasal mucosa and the genital organs in females have been conducted at the clinic of Professor Chrobak for maternity cases. Dr. Fliess of Berlin, although not the first in point of time, has been the most prominent advocate of the theory that there is an intimate relation between these two systems of organs, and maintains that a kind of nasal dysmenorrhœa, or hyperæsthesia of the nasal mucosa, during pregnancy exists in some persons who are not necessarily neurotic. The correctness of his views has, however, been often called in question. Dr. Jerusalem and Dr. Falkner have been trying Dr. Fliess's method of cocainising the tubercula septi nasi in cases of painful menstruation and in prolonged painful labour with gratifying results. In many cases the spontaneous contractions of the uterus after the birth of the child were incapable of expelling the placenta until the nose, and especially the anterior ends of the lower turbinated bone or the tuberculum septi, had been touched with cotton dipped in a 10 per cent. solution of cocaine. The results of these investigations were described to the Clinical Society in a paper by Dr. Jerusalem and Dr. Falkner, who have also written on the subject in the *Wiener Klinische Wochenschrift.* No precautions were taken against suggestion, as the patients had to be informed why their noses were suddenly the object of so much attention. Some degree of toleration of cocaine was observed in a few cases when the initial doses of from three to four drops of a 10 per cent. solution were sufficient only once or twice, and then it became necessary to resort either to a larger dose or to a 20 per cent. solution.

---

[1] THE LANCET, April 7th, 1906, p. 987.

The University of Vienna.

The new calendar of the University of Vienna, which contains the lectures and classes for the summer term, May, June, and July, 1906, has just appeared and shows little difference from that of last year except as regards some minor lectures on diagnosis and chemistry. The extent of the Medical Faculty of Vienna may be estimated from the fact that no less than 32 ordinary and 57 extraordinary professors will lecture to students and graduates during these three months. The total of lectures and classes exceeds 350, and in the work of teaching help is given by the numerous "docenten" and assistants of the various university institutions. The fees for the courses vary a good deal, being very low for the students (from 10*s.* 6*d.* to £1 1*s.*), whereas graduates have to pay from four to eight times that amount. In several classes—for instance, in gynæcology and bacteriology and experimental physiology—the number admitted is limited to six or ten, thus insuring sufficient material and adequate instruction to the students.

An Old Enactment for the Prevention of Dust.

Several medical men have been recently promoting a movement for the diminution of the dust nuisance, but efforts in this direction have been made for a much longer period than is generally recognised at the present time. A quaint document was not long ago brought to light when the librarian of the royal and imperial library found in a bundle of papers an order relative to the abatement of dust. The text of this order prohibits "riding or walking in large groups or driving at a great pace" in certain streets of the city of Vienna and in the ditches of the fortress, as it "produces annoyance to the peaceful citizens and is apt to disseminate pestilence, bad coughs, and fevers, and is generally unfavourable to health." No endeavours have, however, succeeded in exterminating some of the most annoying sources of the Vienna dust nuisance. The situation of the city in a valley between two ranges of chalk mountains, the prevalence of winds coming from the direction of these mountains, the antiquated system of street paving, and the unsatisfactory method of street cleansing all tend to give the beautiful city an unenviable reputation for dust and dust diseases. At one time tuberculous disease of the lungs was here called morbus Viennensis. At present a society for the prevention of dust has been formed with the same object as so many others of a like kind in bygone days. The only tangible result of its existence is the discontinuance of the miserable practice of dust collection in open vans and the substitution of closed dustbins, which are collected without any possibility of the contents being scattered to the winds.

April 30th.

NOTES FROM INDIA.

(FROM OUR SPECIAL CORRESPONDENT.)

A Case of "Sati" in the Punjab.

IT may be remembered that last year a young widow in the presence of a vast concourse of people publicly committed "sati" by consigning herself to the funeral pyre and perished amidst the flames. This occurred as recently last October in the Punjab and shows that the desire to resuscitate this horrible practice still lingers in the minds of the people. Some of her relatives were arrested, admitted the main facts, and were sentenced to severe punishment. Unfortunately, on appeal the sentences have been reduced. The ghastly performance had been advertised in the surrounding villages and the day was a festival day, so that the participation in the crime was premeditated. The magistrate described those who participated in the suicide as "the most wretched specimens of humanity it has ever been my ill fortune to see outside a hospital or asylum, of miserable physique and stunted intellect." The Punjab chief court in reducing their sentences from ten to two years' imprisonment has evidently considered them irresponsible degenerates.

Plague Riot in Seistan.

The outbreak of plague in Seistan has been attended with riot. It is curious to note how often disturbance occurs in the early part of an outbreak. At Nasirabad there were erected temporary shelters for the accommodation of the plague patients and there was also a plague hospital. These have been all wrecked. Objection seems to have been taken to the measures for the suppression of plague instituted by the local authorities. At first there was some anxiety for the safety of the Europeans at Seistan but order was partially restored and Persian troops were sent for.

The Plague Mortality in India.

The development of the annual plague recrudescence still goes on. For the week ending March 31st there were 13,996 cases with 11,823 deaths reported for the whole of India, but these figures do not include Bengal, the Punjab, and Rajputana. The report does not mention Bombay or Calcutta, in both of which cities plague is raging virulently. In Mandalay the outbreak is very severe, all business is suspended, and two-thirds of the population are reported as having fled away. Out of 3000 Chinese only 400 are said to be left. Since the outbreak began 1265 deaths have occurred—a very large mortality for the size of the city. In Rangoon the disease is still prevalent, 318 deaths being reported for March. In Bombay city the mortality is just now very high. Of 1860 deaths for the week ending March 31st 821 were due to plague, but even without these there were some 400 deaths above the average. In Calcutta the plague outbreak seems much less severe. The published figures show it to be less than half in severity to that of last year.

April 13th.

Obituary.

HENRY ALEXANDER GOGARTY, M.D. DUB., L.R.C.S. IREL.

Dr. H. A. Gogarty died at his residence in Ethelbert-road, Canterbury, on April 18th, in his seventy-second year. He had been in weak health for a considerable time, suffering chiefly from cardiac trouble, which caused his friends much anxiety last September and eventually carried him off. Dr. Gogarty received his medical education in Dublin, taking the diploma of L.R.C.S. Irel. in 1853. In 1867 he graduated as M.B. at the University of Dublin and proceeded to the degree of M.D. in 1878. He entered the medical department of the Army as assistant surgeon in 1855 and saw much service during the Indian mutiny, being present at the defeat of the Sealkote mutineers on the banks of the Ravee in July, 1857; he was also present from August 14th at the siege of Delhi and was awarded a medal with clasp. He was for many years attached to the 52nd Light Infantry (now merged in the Oxfordshire Light Infantry) and the Rifle Brigade; he was promoted to be surgeon in 1870 and retired from the Rifle Brigade with the rank of surgeon-major in 1877. He went to Canterbury about 25 years ago when he was appointed one of the honorary physicians to the Kent and Canterbury Hospital, a position which he filled with conspicuous ability until the beginning of 1905, when on his retirement from active work he was elected consulting physician to the hospital. Besides his hospital duties he was also for a long time lecturer on practical medicine at St. Augustine's Missionary Training College, Canterbury. In addition to being a skilful practitioner Dr. Gogarty was a kind-hearted man, honourable in all his dealings, and a faithful friend. He has left a widow, two sons, and two daughters. The funeral took place at St. Martin's, Canterbury, on April 21st.

ROYAL HOSPITAL FOR CHILDREN, BRISTOL.—The annual meeting of the "Ladies Auxiliary" in connexion with this institution was held on April 26th under the presidency of the Duchess of Beaufort. It was reported that during the year the sum of £522 had been raised for the funds of the hospital and that the "needlework guild" in connexion with the society had given 668 garments to the institution.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the Congregation on April 26th the following degrees were *conferred* :—

M.D.—J. F. Alexander, Trinity; E. S. Scott, Pembroke; and G. W. Greene, Downing.
D.Sc.—G. H. F. Nuttall, Christ's.
M.B.—H. M. Wilson, Trinity Hall; F. D. Crew, Emmanuel; and E. W. Sheaf, Downing.
B.C.—W. P. Morgan, Clare; and F. D. Crew, Emmanuel.

UNIVERSITY OF DURHAM.—At examinations for the degree of Bachelor in Medicine held in April the following candidates satisfied the examiners :—

FIRST EXAMINATION.

Elementary Anatomy and Biology, Chemistry, and Physics.—Second-class Honours: Jabez Ethelbert Dainty and Charles Marks, College of Medicine, Newcastle-upon-Tyne. *Pass List*: Frederick Ernest Chapman and Herbert Edward Fullerton, College of Medicine, Newcastle-upon-Tyne; William Reynolds, Guy's Hospital; and William Robert Elstob Unthank and Charles Leslie Wigan, College of Medicine, Newcastle-upon-Tyne.

Elementary Anatomy and Biology.—Everard Cecil Abraham, Isaac Bainbridge, John Akilade Caulcrick, Robert Vickers Clayton, Helen Grace Clark, John Hare, John Parkinson Higham, Howard Tomlin Hunter, Laurence Heber Warneford Iredale, and George Eric Warner Lacey, College of Medicine, Newcastle-upon-Tyne; Herbert Vere Leigh, University College, Cardiff, Samuel Littlewood, George Cuthbert Mura M'Gonigle, Charles O'Hagan, and Eric Hemingway Shaw, College of Medicine, Newcastle-upon-Tyne; Henri René Guillaume Vander Beken, London Hospital and College of Medicine, Newcastle-upon-Tyne; and Stanley Worthington and James Carruthers Young, College of Medicine, Newcastle-upon-Tyne.

Chemistry and Physics.—Eliot Watson Blake, Guy's Hospital; Alexander Hay Bower, Francis Frederick Trevor Hare, and John Howard Owen, College of Medicine, Newcastle-upon-Tyne; Elliot Jessie Ramsbotham, London School of Medicine for Women; Charles Elias Reindorf, College of Medicine, Newcastle-upon-Tyne; and Madeline Rosa Shearburn and Olivia Nyna Walker, London School of Medicine for Women.

THIRD EXAMINATION.

Pathology, Medical Jurisprudence, and Public Health.—Second-class Honours: Gertrude Ethel O'Brien and Stanley Dunn Metcalfe, College of Medicine, Newcastle-upon-Tyne. *Pass List*: Charles Martin Brown, Gilbert Iliffe Cumberlege, and Ronald Martyn Davies, College of Medicine, Newcastle-upon Tyne; William Harold Edgar, St. Mary's Hospital; Helen Mary Gurney and Hubert Shield, College of Medicine, Newcastle-upon-Tyne; and John Franklin Young, Guy's Hospital and College of Medicine, Newcastle-upon-Tyne.

UNIVERSITY OF EDINBURGH.—The following is an official list of those who have completed the first, second, and third professional examinations respectively :—

First Professional Examination.—E. M. Allan, Edward Anderson, F. G. Bell, R. A. Bell, Eveline R. Benjamin, J. G. Boel, C. J. G. Bourhill, A. M Britton, G S. Brown, H. H. Brown, J. F. Brown (with distinction), Peter de Bruyn, B. C. Burke, G. D. Cairns, L. D. Callender, A. F. Calwell, W. W. Carlow, M.A., G. J. Carr, B.A., J. A. H Carter, R. B. Chamberlain, J. P. Charnock, Percy Chisholm, F. O. Clarke, W. G Coltart, E. S. Craig, T. D Crawford, Josias Daneel, William Darlington, James Davie, I. D. Dickson, John Drummond, Isabella G. Emslie, James Erlank, W. J. Feltham, Annie G. Fergus, E. L. Ferguson, J. B Ferguson, F. P. Fouche, C. M. Ganapathy, F. P. Gibson, T. J. Gilmore, J. G. Gow, Colin Grant, R W. Greatorex, Annie C. Greenep, W. P. Grieve, E. B. Gunson, H J. Guthrie, T. E. Guthrie, R H. Hamilton, D. S. Harvey (with distinction), J. B. Haycraft, Alexander Hood, John Hunter, A. P. W Hutton, A. B. Jamieson, A. M Jones, G. J Joubert, Agnes E Keen, T. D. Kennedy, J. C J. Khambatta, S. G. Kriegler, E. O. Lang, D. T. M. Large, Leonard Leslie, A. Sinclair Loutit, J. F. H. Lutze, D. M Lyon (with distinction), K. B. MacGlashan, J. M. M'Keand, A. H. G. Mackintosh, D. J. M'Laren, Elizabeth Macleod, Mary Macmillan, R. C. Malhotra, D. B. Maunsell, G. M. Miller, S. P. Moore, M. M. Morrison, William Morrison, Rhoda M. Murdoch, O. A. J. N Muriset, Kishanlal Nehru, R. M Nicholson, F. H. Noronha, W. H. Pallett, Dora E. Paterson, P. N. Pedersen, A. Z. Phillips, J. A. Pienaar, B.A., C. K. Pole, A. H. Porter, W. D. Reid, D T Richardson, W. S Robertson, Lizzie Rose, William Russell, C. M. Schaffter, J. W. Senter, Daisy L. Shawyer, B.A., Alexander Simpson, F. M Sinclair, D. R. Bedell Sivright, B.A., T. W. Smart, Gertrude M. Smith, T C. Smith, R. O. Spencer, G H Stevenson, John Stevenson (Rosneath street), F. M. Stewart, J. D. G. Stewart, Malcolm Stewart, J. R. Stott, George Tate, L. W. Owen Taylor, R C. Tennent, A. B. Todd, J. J. Tough, C. E Tudehope, Jane A. Walke (Old Regns.), R. C. Wallace, A. M. Warwick, G. A. Wyon, and R. B. M. Yates.

Second Professional Examination.—G. J. Adams, R. C. Alexander (with distinction), H M. Anderson, William Bainbridge, Margaret W. Bartholomew, Lydia D. la Trobe Bateman (with distinction), G L. Batra, A. R. Bearn, James Black, Henry Blyth, A. M. Bose, William Boyd, John Brander, L. A. P. Burt, Eileen Cansfield, J. A. R. Cargill, J. T. Carson, Peter Chalmers, D. G. Cooper, B A., H 6. Cormack, A. C. Court, J. C. Craig, M.A., Emilie C. Creaser, John Crocket, J. M. Dalrymple, Purser Davies, J. M. Denchars, P. S Dias, A. L. Dykes, W. G Evans, John Findlay, Thomas Gardner, A. L. Girdwood, R. L. Girdwood, J. A. Gordon, Peter A. G. M. Grant, J. C. B. Grant, J. K. Hamilton, M.A., James O. Hamilton, Robert Hannah, F. W. Hay, John Hewat, S. W. Hogg, J D. Ingram, K. R. K. Iyengar, F. E. Jardine, J. J. Jervis, W. P. S. Johnson, M. J. Johnston, J. V. Karve, H. W. Kerrigan, Catherine Kirk, M.A., E. W. Kirk, R. A. Krause, F. R. Laing, C. L. Laurent, R. D. Laurie, H. R. Lawrence, M. A. Lindsay, A. S. Macbeth, John Macdiarmid, Ranald MacDonald, R. F. D. Macgregor, W. J. M'Keand, Kenneth Mackenzie (with distinction), A. C. M'Killop, D. R. O. Maclagan, I. R. MacLeod, Ada J. Macmillan, W. M. Macnab, David Macnair, E. E. D. Maconochie, S. E. Malherbe, A. C. Mallace, M.A., John Marshall, R. C. J. Meyer, A. F. Miller, J. A. Mitchell, Flora Morrison, I. A. van Niekirk, E. F. W. Nixey, A. C. Norman, P. G. Palmer, A. B. Pearson, J. H. H. Pearson, A. A. W. Petrie, B. B. Phillips, Laura W. Pugh, J. J van Rensburg, E. W. Richards, W. G. Riley, A. G. Ritchie, Agatha M. Robinson, D. H. Russell, John Scott (with distinction), J. T. Simson, E. W. Smerdon, W. B. Sommers, J. E. Spence, William Stobie, Adam Tait, A. L. Taylor, G. P. Taylor, J. Gordon Thomson, M.A., J. J. Thomson (with distinction), N. G. Thornley, R. W. Lang Todd, Mary M. M. Turpie, Raymond Verel, F. H. de Villiers, A. A. Walbrugh, E. A. Walker, W. O. Walker, H. S. Wallace, L. E. B. Ward, F. K. te Water, W. H. te Water, F. W. Waterworth, Alexander P. Watson, M.A., Hugh B. Watson, M.A., H. L. Watson Wemyss, Adam White, J. L. Masterman Wood, R. L. C. Wuppermann, A. G. Yates, M.A., and W. A. Young.

Third Professional Examination.—J. B. Alexander, J. L. Annan, J. C. Ashton, Ernest Banks, A. C. Barker, C. B. Baxter, A. E. Bennee (with distinction), J. W. Bingham, J. A. Brand, Alexander Bremner, Thomas Buchan, Thomas Burrell, P. D. Cameron, R. J. Chapman, W. G. Cobb, W. D. Coghill, C. E. A. Coldicutt, C. H. Corbett, H. C. D. Cross, Mackenzie Douglas, J. C. Drysdale, G. L. Duncan, A. D. Edington, B.Sc., Robert Edwards, P. A. Erevrard, J. Letitia D. Fairfield, W. P. Ferguson, M.A., B.Sc., Mary S. Finlayson, W. S. Forbes, John Fraser, J. B. Gibson, M.A., R. M. Glover, J. M. Grant, D. G. Gray, A. R. Gunn, D. J. Guthrie, George Henderson, W. S. Heron, A. Fergus Hewat, Matthew Heyns, James R. Hill, J. K. A. Hofmeyr, St G. M. L. Homan, J. H. Horne, Lloyd Hughes, T. J. Hughes, Alexander Hunter, H. B. Hunter, M.A., Spencer Jackson, J. A. Jamieson, R. H. Jamieson (with distinction), Blanche M. L. Johnston, T. Arnold Johnston, W. D. Stoney Johnston, Daniel Johnstone, M.A., G. G. Jolly (with distinction), S. W. Joubert, J. G. de Kock, G. F. V. Leary, J. H. Lechler, David Lees, M.A. (with distinction), Cecil R. Lethem, G. L. Little, K. F. Lloyd, C. W L. Luethgen, G J. Luyt, Thomas Lyon, R. D. M'Allister, L. G. M'Cune, W. S. M'Cune, Angus Macdonald, James F. Mackay, John L. Mackay (with distinction) A. T. Mackenzie, M.A., R. E M'Laren, D. J. M'Rae, Paula Maier, J. A. Manifold, A. H. M. Maxwell, F. W. Michael, G. G. Middleton, Margaret M. Miller (with distinction), A. P. Mitchell, J. A. Morris, John Morrison, James Muckart, Ara G. Murchison, William Murdie, M.A., Meher A. D. Naoroji, Joseph Newall, J. J. H. Nelson, A. T. Paterson, O. F. Pattie (with distinction), J. S. Peebles, G. R. Pillai, W. J. Porteus (with distinction), O. E. Powell, N. H. Prior, D. H. Rai, B.A., W. R. Ridley, Adam N. Robertson, Charles Robertson, David Robertson, W. A. Scobie, Francis L. Scott, W. J. Simpson, J. T. Simson, E. Drybrough Smith, F. F. S Smith, R. A. Spence, Dorothy W. Stevenson, L. H. F. Thatcher, O. A. Thelander, C. P. Theron, David Thomson, William Thomson, W. Wilson Thomson, V. F. Usher, A. M Vlok, Helen M. Wakefield, Martha B. Webb, J. C. B. Williams, and J. L. Wilson.

ROYAL COLLEGE OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the April meetings of the examiners the following candidates passed the respective examinations :—

First Examination (Five Years' Course).—Samuel Ralph Waugh, Toddington, Beds; Hofmeyr Schimper, South Africa; David Lindsay Hutton, Glasgow; Joseph Louis Pinto, India; Gideon Joubert du Preez, Cape Colony; and Willoughby Edward Pellew Briggs, Rochdale.

Second Examination (Five Years' Course).—John Cornock Hawkes, Ireland; Harold Parker Bruce Tait, Jamaica; Franklin Joseph de Souza, Goa, India; Henry William Turner, Glasgow; George William Mason, Pontypool, Mon.; David Welsh, Lanarkshire; Maurice Edward Kayton, Bagdad; Samuel Abeyesundere, Ceylon; Thomas Nicholson Wilthew, Hexham; George Fred. Walker, Bootle; Ferdinand Byrne, Liverpool; William Rich Mackenzie, Belfast; and Robert M'Connell Blair, Glasgow.

Second Examination (Four Years' Course).—William Clegg Newton, Manchester, and Patrick John Alexander Curtin, India.

Third Examination.—James Fenbair Jefferies, Cork; Matthew Hamilton Fleming, Avondale; Thomas Bertram Eames, Kearsley; George Coats, Paisley; Walter Ernest Barrett, Leeds (with distinction); Graham Smith, Ashbourne, Derby; John Moncrieff Muir, Kilmarnock; Evan Alan Sevill Shaw, Callao, Peru; Alex. O'Flaherty, Ireland; Phiroza Behramji Malabari, India; Ellis Thomas Evans, Wales; Fred. Garnet Allan, Whaley Bridge, Cheshire; James Sullivan, Co. Cork; and Thirukama Sundara Reddy, Madras.

Final Examination and admitted Licentiates of the three Coöperating Authorities.—Edward Arthur Smith, Southport; James Logan, Maryhill; Charles Conway Fitzgerald, Belfast; Daniel Thomas Henry Croly, Dublin; John Hamilton Fullarton, M.A., D.Sc., Brodick; Andrew Ferd Garrard, Langside, Glasgow; Norman Bennington Watch, Partick; Alexander Brown, Galston; Francis William Cooper, Enniskillen; and Hormusji Jamshadji Chenoy, Edinburgh.

HONOUR TO AN ARBROATH MEDICAL MAN.—Dr. T. F. Dewar of Arbroath who was recently appointed medical officer of health of the county of Forfar, was honoured by his fellow townsmen on the evening of April 26th, when a company of over 100 representative citizens entertained him to a complimentary dinner in the White Hart Hotel.

ROYAL INSTITUTION.—The annual meeting of the members of the Royal Institution was held on May 1st, the Duke of Northumberland, K.G., being in the chair. The annual report of the committee of visitors for the year 1905, testifying to the continued prosperity and efficient management of the institution, was read and adopted, and the report on the Davy Faraday Research Laboratory of the Royal Institution, which accompanied it, was also read. 45 new members were elected in 1905. 63 lectures and 19 evening discourses were delivered during the year. The books and pamphlets presented amounted to about 254 volumes, making, with 697 volumes (including periodicals bound) purchased by the managers, a total of 951 volumes added to the library in the year. Thanks were voted to the president, the treasurer, and the honorary secretary, to the committee of managers and visitors, and to the professors, for their valuable services to the institution during the past year. The following gentlemen were unanimously elected as officers for the ensuing year:—President: the Duke of Northumberland. Treasurer: Sir James Crichton-Browne. Secretary: Sir William Crookes. Managers: Sir William de W. Abney, the Right Hon. Lord Alverstone, the Right Hon. Earl Cathcart, Dr. A. H. Church, Dr. F. Elgar, Dr. D. W. C. Hood, Mr. M. Horner, Sir William Huggins, the Right Hon. Lord Kelvin, Mr. H. F. Makins, Dr. Ludwig Mond, Sir R. Douglas Powell, Bart., the Right Hon. Lord Sanderson, Mr. Alexander Siemens, and the Right Hon. Sir James Stirling. Visitors: Dr. J. Mitchell Bruce, Mr. Dugald Clerk, Sir John George Craggs, Mr. H. Cunynghame, Mr. G. F. Deacon, Mr. E. Dent, Rev. J. H. Ellis, Mr. R. K. Gray, Mr. C. E. Groves, Mr. F. G. Henriques, Mr. A. C. Ionides, Mr. C. E. Melchers, Mr. E. R Merton, Mr. H. Swithinbank, and Mr. G. P. Willoughby.

CENTRAL MIDWIVES BOARD.—A meeting of the Central Midwives Board was held on April 26th, at 6, Suffolk-street, Pall Mall, Dr. F. H. Champneys being in the chair. A letter was read from a certified midwife saying that since the Midwives Act came into force it had made, so far, very little difference in the practice of midwives. It was also stated in the letter that in the locality where the writer practised the untrained women still practised and that with one exception the medical men did not approve of practising midwives. They informed prospective mothers that if the certified midwives summoned medical men in difficult cases the medical men would double their fees. It was further pointed out in the letter that the poor folk on 12*s.* a week were frightened that the certified midwife would send for a medical man and so let them in for a bill for 2 guineas. Dr. J. Ward Cousins said that the important question of payment to medical men called in by midwives in difficult cases was raised by the letter and the matter involved the satisfactory carrying out of the Midwives Act. If the fee for the medical man called in by the midwife was paid by the patient the difficulty was solved because no one would object to the medical man being paid in that manner. Cases, however, had occurred in which certified midwives had been compelled to pay the fee of the medical man summoned before he would assist the midwife. Dr. Ward Cousins did not think that the medical profession expected a medical man called in to an emergency case of difficulty to be paid by the midwife who called him in. The subject was one that had to be considered by the Central Midwives Board and it had to be remembered that the difficulty in regard to payment to medical men in these cases was felt most acutely in country districts where practitioners had to travel sometimes many miles at night without receiving any fee. In Cardiff and Liverpool the local supervising authorities had made arrangements for the payment of medical fees in these cases. The question was a critical one because medical men were required in every sense of the word to give assistance in these cases, and the Central Midwives Board ought to insist that some provision should be made by the local supervising authorities for that purpose. Miss J. Wilson asked under what powers Liverpool and Cardiff arranged for the payment of medical men when called in. The Secretary explained that the accounts of county councils were subjected to the Local Government Board auditors and such payments would be surcharged, but the boroughs were not in that position, for they elected their own auditors whose reports need not be regarded by the boroughs. If rich and large boroughs chose to break the law it was their own matter. Mr. E. Parker Young moved that the matter should be referred to the Standing Committee to consider and report what amendment of the Act was desirable.—Dr. Ward Cousins seconded the motion which was carried.

APOTHECARIES' HALL OF IRELAND.—Mr. D. J. Boyle having completed his final examination has been granted the diploma to practise in medicine, surgery, midwifery, and pharmacy.

Mr. Charles Arthur Wigan, M.D. Durh., M.R.C.S. Eng., L.S.A., has been elected chairman of the Portishead (Somerset) district council.

LITERARY INTELLIGENCE.—The annual subscription to the *Paris Medical Journal*, the appearance of which we notice elsewhere, is 12*s.* Communications should be addressed to the editors, Dr. Gros, 28, Rue de Ponthieu, or Dr. Warden, 9, Rue de Chalgrin, Paris.

TIVERTON INFIRMARY.—Considerable improvements are being carried out at the Tiverton (Devon) Infirmary. Mr. J. Coles has presented a house adjoining the institution which is to be utilised as a nursing home. He has also given £500 for improvements and this will be expended upon furnishing the nursing institute, enlarging the children's ward, and making other improvements in the infirmary. An additional £300 will be required and it is hoped to raise this sum by means of a bazaar.

MEDICO-PSYCHOLOGICAL ASSOCIATION.—The south-eastern division of this association met at the Herts County Asylum, Hill End, near St. Albans, on April 25th. There was a large attendance of members. After the wards had been inspected Dr. A. N. Boycott hospitably entertained the company to lunch. At the meeting a resolution was passed recommending the association to take the opinion of the members as to the new psychological tables. Dr. W. H. B. Stoddart read a paper entitled "Instincts: a Psycho-Physical Study in Evolution and Dissolution," and compared the mental evolution of the child with the inverse process occurring in the dissolution of dementia. Dr. D. G. Thomson introduced a discussion on the question of the preparation of nurses for the examination for the medico-psychological certificate and on the conduct of the examination. Votes of thanks to Dr. Percy Smith, the chairman, and to Dr. Boycott terminated the proceedings.

ROYAL EYE HOSPITAL, LONDON.—In connexion with the courses of instruction in ophthalmology which are now being given at this hospital Sir William J. Collins gave the inaugural lecture on April 30th before an appreciative audience of about 30 students. Professor M. M. McHardy, the senior surgeon of the hospital, occupied the chair. The lecturer took for his subject the Study of Ophthalmology. In the course of his lecture Sir William Collins said that the study and treatment of diseases of the eye were among the earliest to lend themselves to the handling of the specialist. The introduction of the ophthalmoscope served to accentuate the differentiation of ophthalmology from the common stock of medical knowledge. The lecturer emphasised the fact that ophthalmic surgeons should keep the base of their speciality broad, lest they lose something of philosophic insight, of that power of seeing the *one in the many*, that breadth of view which the history of discovery tells us has ever been the source and inspiration of new truth. It was pointed out that for a fruitful and rational study of ophthalmology it was imperative that we should always retain, on the one hand, close touch with scientific method as recognised in other departments of knowledge and investigation and, on the other hand, a broad nexus between ophthalmology and general surgery and medicine. The lecturer then illustrated by examples the relationship of the diseases of the maxilla and of the nasal fossæ to those which might follow in the orbit, and he also emphasised the close relationship between the various forms of ophthalmoplegia and such diseases as locomotor ataxia and general paralysis of the insane. At the close of the lecture Professor McHardy proposed a vote of thanks to the lecturer, which was seconded by Mr. L. Vernon Cargill, who also briefly explained to the audience that it had been decided to give systematic instruction in eye diseases at the Royal Eye Hospital and that this would be carried out by Mr. G. T. Brooksbank James, Mr. Arthur W. Ormond, and Dr. H. Willoughby Lyle, while the senior surgeons would from time to time deliver special lectures and give clinical demonstrations. Mr. Cargill stated that the clinical material was abundant, which was shown by the fact that last year more than 23,000 new cases were treated in the out-patient department. Full particulars of these courses may be obtained from the honorary secretary, Mr. Ormond.

STRATTON COTTAGE HOSPITAL.—At the annual meeting of the supporters of the cottage hospital at Stratton in Cornwall the committee in its report stated that it wished to record its deep sense of gratitude to Mr. J. Montague Braund, who had resigned the post of honorary medical officer to the institution after 38 years' service. The committee further said that Mr. Braund had not only given much time to the work of the hospital but had also shown a constant interest in its welfare.

JUBILEE OF THE LONDON BIBLE WOMEN AND NURSES' MISSION.—The Marquis of Northampton, president of this mission, has issued to the press an earnest appeal on behalf of the Jubilee Fund. The mission was founded in 1857 and in 1868 district nursing work was added. There is also in connexion with the mission a convalescent home which annually receives 300 patients. A sum of at least £14,000 a year is required to carry on the beneficent work of the mission. Subscriptions should be sent to the honorary secretary, 2, Adelphi-terrace, Strand, W.C., or to Lord Kinnaird, the treasurer, at the bank of Messrs. Barclay and Co., 1, Pall Mall East.

LEAMINGTON SPA.—It is not impossible that in time we may see our British watering places sought after by foreigners as much as foreign watering places are by the inhabitants of these islands. Although the waters, the methods of treatment, and the social attractions may be as great at home as abroad, yet many persons will prefer to go abroad on account of the change of scene, of manners, and of food which they obtain. But British watering places are certainly waking up and in proof of this we have just received some publications relating to Leamington Spa. The enterprising town council, to whom the baths belong, has, with the assistance of the medical practitioners of the town, drawn up a book of order forms for the baths whereby any practitioners may give exact directions for the kind of bath he wishes his patient to have, besides the other methods of treatment which are given. Such are massage and the application in its various forms of electricity. These latter have been quite recently introduced. Besides its purely medical side Leamington possesses various social attractions and is one of the great hunting centres of England. The town council, we think, deserves that success in making Leamington a sought for health resort which it is evidently doing its best to attain.

ROYAL PORTSMOUTH HOSPITAL.—On April 25th, in the presence of a large assemblage, the Mayor of Portsmouth, Sir George Couzens, laid the memorial stone of a new operating theatre and corridor of the Royal Portsmouth Hospital. Mr Bramsdon, M.P., chairman of the governors, presided and spoke of the splendid work which had been done during the last 50 years in the old theatre, but the rapid strides in surgical science had made it obsolete and necessitated the erection of a well-equipped operating theatre thoroughly up to date. The contract cost of this was £2075 He stated that Mr. H. Rundle had taken advantage of the fact that building operations were in progress and had generously given a museum and library, which would be a valuable addition to the usefulness of the hospital. The new operating block, together with the corridor connecting the two existing ward blocks, which were completed in 1899, is the second portion of the scheme for the entire reconstruction of the hospital and contains, besides the operating room, a room for the administration of anæsthetics, a surgeon's room, and a room for sterilising dressings, instruments, &c. The whole block is constructed of fireproof materials and all the walls and ceilings will be lined with opalite (glass), a light green five feet high and white above, and all angles will be well rounded. The floors will be laid in Rust's vitreous glass mosaic paving, also with rounded angles. The artificial lighting will be electric and special arrangements will be made for the supply of electric current for motors, lamps, and cauteries. The warming and ventilating will be by means of hot-water coils. Behind each of these coils will be an opening containing an electric fan which will pump air into the room, the air having to pass through a screen formed of muslin for the purpose of cleaning it. These screens are arranged so that the muslin can be removed and a new piece fixed in a few minutes. In the ceiling at the back of each room is an extract shaft leading to a box on the roof, in which is another fan drawing the air outwards; thus a continual gentle current of air will be passing through these rooms when they are in use. It will be possible to change the air in these rooms five times in every hour. The floors of all rooms are so arranged that all the walls can be washed down with a hose pipe and the water taken away in the drain. The new buildings, which will be completed by Michaelmas next, have been designed by Messrs. Young and Hall.

SANITATION AND PUBLIC HEALTH IN FRENCH WEST AFRICA.—Captain Cromie, British Consul General at Dakar, in his annual report to the Foreign Office just received, mentions that in April, 1904, an ordinance was published laying down regulations for the preservation of public health with the special object of fighting malaria by the destruction of mosquitoes, of preventing epidemic maladies, and of enforcing vaccination. At the same time municipal sanitary services and sanitary brigades were created. These bodies began their work in Senegal on Jan. 1st, 1905, and were successfully formed in the other colonies. It is difficult as yet to give an account of the results obtained by this measure but in the case of Dakar they seem to have been favourable. In spite of the numerous public works, which have made of Dakar a vast workshop, which have drawn a large outside population, both European and native, and have opened up the ground in all directions—without being stopped during the rainy season, when the public health is at its worst—the gross number of admissions to hospital from Jan. 1st to Oct. 31st, 1905, diminished by 210. Malarial patients were reduced from 407 in 1904 to 242 in 1905 and private practitioners give similar results. The general mortality declined from 12 5 to 10 1 per cent. One case of yellow fever occurred in 1905 but thanks to the very vigorous measures immediately taken and also to the improved sanitary conditions, this case, instead of as in former years leading to an epidemic, remained quite isolated. Nor has the public health of the native population been neglected In addition to the medical corps of the colonial army, a number of civil surgeons have been appointed with the special object of looking after the health of the natives in the interior districts. In addition a corps of native assistant doctors is to be formed. Each of the civil surgeons will have one or more native pupils whom he will instruct in general practice. Those who show sufficient promise will subsequently undergo instruction in the chief hospital of the colony, after which they will be stationed in districts where their services are required. Special attention will be directed to reducing the percentage of infant mortality, which is very high, and also to the encouragement of vaccination. For this latter purpose a vaccine station is to be established in each colony. Altogether a sum of £48 280 is devoted to sanitary services in the general budget for 1906, apart from the credit for those services in the various local budgets.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

A Shops Bill.

THE Bill which Sir CHARLES DILKE has introduced in the House of Commons to amend the law relating to shops is drawn on the same lines as the Bill introduced in the session of 1904. The first three clauses have been modified in consequence of the passing of the Shop Hours Act, 1904. It is proposed by the Bill to amend the Shop Hours Act by making it compulsory on local authorities to make closing orders for their areas, while empowering them to refer to the ratepayers the questions whether any order shall come into operation at all and whether any alteration shall be made in the proposed order. The Bill determines the latest closing hours for each day which may be fixed by the local authority, leaving the local authority free to distribute the particular closing hours over the different days of the week. In order to insure uniformity as far as is convenient, it is proposed to give control to authorities administering wide areas—viz., the County Council in London, and elsewhere to the county or borough council.

The Bill repeats the miscellaneous proposals of the Bill of 1904 with regard to the Sunday closing of shops, the prohibition of the employment of children under 14 years of age, the hours of employment in shops, and their sanitary condition, ventilation, and conveniences. It is so designed as to give to persons employed in shops some of the protection which the existing law gives to persons employed in factories and workshops.

Cigarette Smoking by Juveniles.

An influential Scotch deputation waited upon the Lord Advocate on April 27th to urge upon him the propriety of supporting Dr. Macnamara's Bill, which makes it an offence for a person to sell tobacco to boys and girls under 16 years of age. The representative of the Glasgow School Board expressed the opinion that the cigarette habit among children would not be removed unless the use of tobacco by children were made an offence against the children themselves. In his reply the Lord Advocate acknowledged that Parliament and the public had been apprised by the reports of the Royal Commission on Physical Training and the Departmental Committee on Physical Deterioration of the seriousness of the matter from the point of view of the physical well-being of the youth of the country. But he also pointed out that nothing had been laid before Parliament in the shape of a report which favoured the idea of making young people criminals for smoking cigarettes. The practical question was whether they would get Parliament to sanction a proposal making it a penal offence to supply tobacco and its manufactured products to young people under 16 years of age. A few years ago such a proposal would have been a hopeless one but he felt bound to confess that the proved evidence of physical deterioration dissipated entirely the idea that the grievance was a negligible one. Personally he approved of the principle of Dr. Macnamara's Bill and he promised to suggest to the Secretary for Scotland the desirability of doing something to back up Dr. Macnamara's efforts.

HOUSE OF COMMONS.

Thursday, April 26th.

Physical Deterioration.

Mr. Weir asked the Secretary for Scotland whether the Local Government Board for Scotland had yet arranged to issue to parochial medical officers, sanitary inspectors, and inspectors of poor leaflets containing the opinions of the Committee on Physical Deterioration relative to ventilation and the bringing up of young children, with a view to the dissemination of information on these subjects.—Mr. Sinclair answered: The Board has prepared and will shortly issue a leaflet on the management of young children. It has already issued a comprehensive circular on the control of pulmonary tuberculosis, and it is now considering what further measures may be recommended.

The Central Midwives Board and Poor-law Infirmaries.

Mr. Helme asked the President of the Local Government Board whether, having regard to the refusal of the Central Midwives Board to recognise certain of the large Poor-law infirmaries as training institutions, he would have a return prepared showing the names of the institutions recognised as training institutions by the Central Midwives Board together with the number of midwifery cases in each.—Mr. John Burns answered: The Lord President of the Council is the Minister concerned with the Central Midwives Board and the matter referred to in the question is therefore for him. I understand, however, that there would be no objection on his part to give the information desired.

Friday, April 27th.

Sleeping Sickness in Africa.

Mr. Rees asked the Under Secretary of State for the Colonies whether special measures were being taken to guard against the spread of the sleeping sickness into British Central Africa Protectorate and North-Eastern Rhodesia by the tsetse fly or by other agencies, and whether the effect of the game preserves at Chiromo had been considered in connexion with this contingency.—Mr. Churchill answered: No apprehension has hitherto been expressed by the administration of the British Central Africa Protectorate or that of North-Eastern Rhodesia as to the spread of sleeping sickness into those territories, nor has the Commissioner of British Central Africa Protectorate recommended the adoption of measures to guard against it. Complaints have been made in one quarter in the Protectorate that the Elephant Marsh game reserve at Chiromo harbours the tsetse fly but the suggestion is denied by the Commissioner.

Monday, April 30th.

Vaccination in the Army.

Mr. Weir asked the Secretary of State for War whether he could state what quantity of glycerinated calf lymph was produced at the Army and Navy Vaccine Institute last year, the number of tubes used during the year at military stations, the number sold, and to whom.—Mr. Haldane answered: The quantity produced was sufficient for 107,766 vaccinations; the number of tubes used during the year at military stations was 67,635. No lymph produced at this establishment is sold.

Tuesday, May 1st.

Control of Pulmonary Phthisis.

Mr. Weir asked the Secretary for Scotland whether in view of the statement contained in the public health circular of March 10th last, entitled "Administrative Control of Pulmonary Phthisis," he would state what arrangements would be made for the notification of the disease in each of the six crofting counties.—Mr. Sinclair replied: The question whether the Infectious Disease (Notification) Act should be extended to include consumption is one for the decision of the local authorities concerned. The procedure required to be carried through is set forth in Section 7 of the aforesaid Act. I have also to refer the honourable Member to Part IV. of the Local Government Board's circular of March 10th last to which he alludes.

Administration of the Vaccination Act.

Mr. Wilkie asked the Secretary for Scotland whether he was aware that, in the administration of the Vaccination Act in Scotland, prosecutions and imprisonments of respectable citizens had recently occurred because of their conscientious objections to have their children vaccinated; and would he issue an order that, pending the promised inquiry on this matter, these prosecutions and imprisonments would be suspended.—Mr. Sinclair answered: I have no information as to the particular cases to which the honourable Member alludes. The parish councils in Scotland have no power to make exception in the case of conscientious objectors. Prosecutions and imprisonments could not be suspended without alteration of the law. The Local Government Board for Scotland has from time to time advised parish councils that they may exercise a reasonable discretion in the matter of enforcing the statutory penalties both in the case of a prosecution for failure to vaccinate a second child and in the case of a second prosecution for the same child. In giving this advice the Board has pointed out that, as default generally arises from negligence rather than from conscientious objection on the part of parents, it will be the duty of parish councils to use the most careful discretion where they relax the strict letter of the law in any case which may be brought before them.

Mr. Wilkie also asked the Home Secretary whether, in view of the manner in which the Vaccination Act had been administered and the treatment to which some conscientious objectors had been subjected, mainly owing to lack of uniformity in administration, he would in the circular he was about to issue, give instructions as to the manner of examination of poor applicants and arrange that whatever ameliorative administrative improvements were issued should be made applicable to Scotland, where recently respectable citizens had been imprisoned because they held conscientiously that this practice was not only useless but dangerous.—Mr. Gladstone answered: In the circular which I am about to issue I propose to draw the attention of magistrates to what I am advised is the real meaning and intention of the Act and to suggest considerations which may properly be taken into account in dealing with applications; but I have no authority to give any instructions in the matter. The Act does not extend to Scotland and the latter part of the question should be addressed to the Secretary for Scotland.

BOOKS, ETC., RECEIVED.

Miller, T. Maskew, 120, Adderley-street, Capetown.

Bantu Folk Lore (Medical and General). By Matthew L. Hewat, M.D. Price 7s. 6d. ("Copies obtainable through Messrs. J. and A. Churchill, London.")

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.

ADAMS, G. BASIL D., B.M., B.Ch. Oxon., has been appointed Assistant Resident Medical Officer at the King Edward VII. Sanatorium, Midhurst, Sussex.

ASHWIN, R. H., M.B. Lond., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Market Weighton District of the county of York.

AUDEN, G. A., M.D., B.C. Cantab., has been elected Assistant Honorary Medical Officer to the York County Hospital.

BRISCOE, WILLIAM THOMAS, M.D., M.Ch. Dub., has been appointed Medical Officer for the Pewsham District by the Chippenham (Wilts) Board of Guardians.

BOND, FRANCIS THOMAS, M.D. Lond., M.R.C.S., F.R.S. Edin., has been re-appointed Medical Officer of Health by the Cirencester Rural District Council.

CARDOZO, S. N., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer and Public Vaccinator for the Northmolton District by the Southmolton (Devon) Board of Guardians.

HARDING, CHARLES HEADLEY, M.R.C.S., L.R.C.P. Lond., has been appointed Medical Officer to the Northern Division of the Whittlesea Union and Public Vaccinator to the Whittlesea Rural District.

HARTFORD, A. H. B., L.R.C.P. & S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Christchurch District of the county of Hants.

MACKEOWN, W. J., B.A., M.B., B.Ch. R.U.I., has been appointed Senior Assistant Medical Officer to the County Asylum, *Fareham*, Hants.

OLLERENSHAW, ROBERT, M.B., Ch.B. Vict., has been appointed Senior House Surgeon to the Liverpool Infirmary for Children.

RICHARDSON, R. R., L.D.S. R.C.S. Eng., has been appointed Assistant Honorary Dental Surgeon to the York County Hospital.

RENTZSCH, SIGISMUND HENRY, L.R.C.P. Lond., M.R.C.S., has been appointed *Honorary* Medical Officer to the Stratton (Cornwall) Cottage Hospital.

ROLSTON, JOHN R., M.R.C.S., L.R.C.P. Edin., has been appointed Honorary Ophthalmic Surgeon to the Royal British Female Orphan Asylum, Devonport.

THOMAS, H. MORRISTON, M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon at the Royal National Orthopædic Hospital.

WAGGETT, ERNEST, M.B., B.C. Cantab., has been appointed Surgeon to the newly constituted Department for Diseases of the Throat, Ear, and Nose at Charing Cross Hospital.

WENHAM, SIDNEY, M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer at Charing Cross Hospital.

WILKINS, ERIC M., M.B. Vict., M.R.C.S., has been appointed Junior Assistant Medical Officer to the Monsall Fever Hospital, Manchester.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Senior and Junior Resident Medical Officers for six months. Honorariums at rate of £20 and £10 a year respectively, with board and lodging.

BIRKENHEAD BOROUGH HOSPITAL.—Junior Resident House Surgeon. Salary £80, with fees.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—Resident Surgical Officer. Salary £100 per annum.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES, John Bright-street, Birmingham.—Clinical Assistant. Honorarium at rate of 52 guineas per annum.

BRECKNOCK COUNTY AND BOROUGH INFIRMARY.—Resident House Surgeon, unmarried. Salary £100 per annum, with apartments, board, attendance, fire, and gas.

BURLEY-IN-WHARFEDALE, SCALEBOR PARK (PRIVATE ASYLUM).—Assistant Medical Officer, unmarried. Salary £150 per annum, with board, apartments, attendance, &c.

BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Physician, unmarried. Salary £80 a year, with board and lodging.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Resident Medical Officer. Salary £100 per annum, with board, &c. Also Physician to Out-patients. Also Surgeon Dentist.

COLCHESTER, ESSEX AND COLCHESTER GENERAL HOSPITAL.—House Physician. Salary £80 per annum, with board, washing, and residence.

COVENTRY AND WARWICKSHIRE HOSPITAL.—Junior House Surgeon for six months, renewable. Salary £80 per annum, with rooms, board, washing, and attendance.

DEVON COUNTY ASYLUM.—Third Assistant Medical Officer. Salary £125, rising to £155 per annum.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with board and lodging.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £40 per annum, with residence, board, and washing.

FAREHAM, HANTS COUNTY ASYLUM.—Second Assistant Medical Officer, unmarried. Salary £175 per annum, with apartments, board, washing, and attendance.

GOSFORTH, NEWCASTLE-ON-TYNE CITY ASYLUM.—Assistant Medical Officer, unmarried. Salary £150 a year, rising to £250, with apartments, board, and laundry.

HARTSHILL, STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with board, apartments, and washing.

ITALIAN HOSPITAL, Queen's-square, London, W.C.—Honorary Assistant Physician.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £80 per annum, with board and residence.

MAIDSTONE, WEST KENT GENERAL HOSPITAL.—Senior House Surgeon, unmarried. Salary £100 per annum, with board and residence.

MANCHESTER AND SALFORD HOSPITAL FOR SKIN DISEASES.—House Surgeon. Salary £75 per annum, with board and residence.

METROPOLITAN ASYLUMS BOARD, Downs School, Sutton, Surrey (for Children with Ringworm).—Assistant Medical Officer. Salary £250 per annum and dinner.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer. Salary £80 per annum, with board, attendance, and washing.

NATIONAL DENTAL HOSPITAL AND COLLEGE, Great Portland-street, W.—Anæsthetist.

PLYMOUTH, SOUTH DEVON AND EAST CORNWALL HOSPITAL.—Assistant House Surgeon for six months, renewable. Salary at rate of £50 per annum, with board, residence, and washing.

ROYAL FREE HOSPITAL, Gray's Inn-road, W.C.—Assistant to the Clinical Pathologist (salary £50 per annum); also Junior Obstetric Assistant and Assistant Anæsthetist. All females.

SHEFFIELD, ROYAL INFIRMARY.—Junior Assistant House Surgeon. Salary £65 per annum, with board, lodging, and washing. Also Junior House Physician. Salary £80 per annum, with board, lodging, and washing.

SHEFFIELD UNION HOSPITAL.—Resident Medical Officer. Salary £200 per annum, with apartments, rations, &c. Also Resident Assistant Medical Officer. Salary £120 per annum, with apartments, rations, &c.

SOCIETY OF APOTHECARIES OF LONDON.—Examiner in Midwifery.

SURREY DISPENSARY, Southwark, S.E.—Resident Medical Officer. Salary £140 per annum, with apartments, coals, gas, and attendance.

SWANSEA GENERAL AND EYE HOSPITAL.—House Surgeon. Salary £75 per annum, with board, apartments, washing, and attendance.

TAUNTON AND SOMERSET HOSPITAL, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

VICTORIA HOSPITAL FOR CHILDREN, Tite-street, Chelsea, S.W.—Honorary Anæsthetist. Also Surgeon to In-patients. Also House Surgeon.

WELLS, SOMERSET AND BATH ASYLUM.—Second Assistant Medical Officer. Salary £150, rising to £250 per annum, with board, lodging, washing, and attendance.

WEST BROMWICH DISTRICT HOSPITAL.—Resident Assistant House Surgeon, unmarried. Salary £50 per annum, with board, residence, and washing.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, 73, Welbeck-street, W.—Clinical Assistant.

WESTERN GENERAL DISPENSARY, Marylebone-road, N.W.—Honorary Surgeon.

WIGAN, ROYAL ALBERT EDWARD INFIRMARY AND DISPENSARY.—Junior House Surgeon. Salary £80 per annum, with board, washing, and apartments.

Births, Marriages, and Deaths.

BIRTHS.

GOUGH.—On April 24th, at Glenallen, Torquay, the wife of John Harley Gough, M.D., B.Sc., F.R.C.S.E., of a son.

JOHNSTON.—On April 24th, at Corstorphine House, Corstorphine, N.B., the wife of T. N. Johnston, M.B., C.M., F.R.S.E., of a daughter.

LAY.—On April 25th, at Peasenhall, Saxmundham, Suffolk, the wife of Charles E. Lay, L.R.C.P., L.R.C.S. Edin., L.M., of a daughter.

PEDLEY.—On April 22nd, at The Terrace, Tonbridge, Kent, the wife of G. A. Pedley, M.R.C.S., L.R.C.P., Lond., &c., of a son.

MARRIAGES.

ALDERSON—SWINDALE.—On April 26th, at St. Margaret's, Ipswich, Percy Francis Alderson, Surgeon, R.N., to Kathleen Ellen Kay, fifth daughter of J. Swindale, M.R.C.S., Warrington-road, Ipswich.

PATON—KIRKWOOD.—At Skelmorlie, on April 26th, by the Rev. John Hunter, D.D., Leslie Paton, M.B., F.R.C.S., of 1, Spanish-place, Manchester-square, W., to May, daughter of the late Richard Reid Kirkwood, West India Merchant.

STEELE—ROGERS.—On April 26th, at St. Peter's, Eaton-square, S.W., by the Rev. F. F. Kelly, LL.D., assisted by the Rev. the Precentor G. G. Wilkinson, Charles Francis Steele, M.B. London, M.R.C.S., L.R.C.P., eldest son of Charles Steele, M.D., of Clifton, to Anita Russell Rogers, youngest daughter of the late Edward Drewer Rogers, D.L., of Rockley, Denmark Hill. Foreign papers please copy.

THOMPSON—DAVIES.—On April 25th, at St. Paul's Church, Helsby, Peter Thompson, M.D., Professor of Anatomy, King's College, London, to Nessy, the eldest daughter of Mr. G. L. Davies, J.P., The Old Hall, Helsby, Cheshire.

THOMPSON—HOOPER.—On April 26th, at the parish church, Ripley, Derbyshire, by the Rev. E. T. Page, Walter Thompson, F.R.C.S. Eng., of 4, Park-square, Leeds, youngest son of the late Samuel Thompson of East Rigton, Yorkshire, to Ann Elizabeth Hooper, M.B., B.S. Lond., daughter of Marshall Hooper, J.P., of Ripley, Derbyshire.

DEATH.

BATEMAN.—On April 25th, at Woodgate, Somerset-road, Ealing, Colonel Daniel Frederick Bateman, I.M.S., in his 66th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

AN UNFORTUNATE CIRCULAR.

To the Editors of THE LANCET.

SIRS,—With reference to the paragraph in your issue of the 28th instant permit me to say that this has caused Dr. O'Connor as much annoyance as it has caused me surprise. I am entirely responsible for the circular referred to, which was issued in the interests of the *tenants of St. James' Court alone, to inform them of* a local advantage which tenants in a huge residential property such as this invariably expect to find and about which prospective tenants make a point of inquiring before arranging a tenancy of a flat. I cannot quite imagine why from the communication you have received alone you should criticise my circular in such a manner, my action being merely a businesslike one in the interests of the property and not in the least degree of interest to any medical body. No such arrangement had previously existed with any particular medical attendant and when it was concluded with Dr. Moylo O'Connor it was my duty at once to inform the tenants. That this is not an uncommon or unusual course the pamphlet I am sending you herewith, relating to another of the largest residential properties in London, will demonstrate to you, the name, qualifications, and previous experience of the medical attendant being fully stated in the pamphlet which is handed to every tenant and every inquirer in connexion with the property in question. No doubt in these circumstances you will do Dr. O'Connor and myself the justice to explain the true position to your readers and disabuse their minds of the erroneous impression evidently conveyed to you by a medical man who was not successful in securing this position himself.—I am, Sirs, your obedient servant,

J. MUNRO ROGER,
Resident Estate Manager, St. James' Court.
St. James' Court, Buckingham Gate, S.W., April 30th, 1906.

*** A pamphlet forwarded to us later by Mr. Munro Roger shows that Queen Anne's Mansions, Westminster, advertises for the benefit of those whom it may concern the fact that a medical man (name given) "is in residence at the mansions and his services can be obtained at any moment."—ED. L.

THE MEDICAL TERMS OF THE EPISTLE TO THE HEBREWS.

To the Editors of THE LANCET.

SIRS,—I am anxious to discover the name of the author of a monograph on "The Medical Terms in the Epistle to the Hebrews." I am under the impression that some years ago (I fancy about six) I saw the work referred to in an obituary notice of its author in your columns.

I am, Sirs, yours faithfully,
April 30th, 1906. M.D.

*** *Possibly some of our readers can assist our correspondent.* The resemblance between the language of the Gospel according to St. Luke and that of the Epistle to the Hebrews has been insisted upon by many writers, from Clement of Alexandria downwards.—ED. L.

AN EXHIBITION OF LEADLESS GLAZE.

AN exhibition of newest designs in leadless glazes was opened at 25, Chepstow Mansions, Chepstow-place, London, W., on May 2nd and will remain open until May 19th. We understand that considerable strides have recently been made in the introduction of pottery, both of a useful and an ornamental character, in the *manufacture of* which there is no danger to the workers in the dipping house of poisoning by contact with raw lead compounds.

MONSTERS.

To the Editors of THE LANCET.

SIRS,—Your correspondent "X" will find Hirst and Piersol's "Human Monstrosities" (Pentland) very useful. There is an excellent article on Teratology in Todd's "Cyclopædia of Anatomy and Physiology." Geoffrey Saint-Hilaire's book, "*Histoire des Anomalies*," published in 1832, is unrivalled. An interesting old work on the subject, published in 1665, is Licetus' "De Monstris."

I am, Sirs, yours faithfully,
F.
May 1st, 1906.

MISS WESTON'S WORK IN THE ROYAL NAVY.

Miss Weston's work at the Sailors' Rests and elsewhere on behalf of the seamen of the Royal Navy is well known to our readers, for it has often been mentioned favourably in our columns. On Tuesday last, May 1st, the annual meeting was held at Portsmouth, when both Miss Weston and her co-trustee, Miss Wintz, were able to give a thoroughly satisfactory account of their labours to an enthusiastic audience. The success achieved during the past year was remarkable. The visit of the French fleet to Portsmouth last summer was the occasion of much hospitality at the Royal 'Sailors' Rest. Some thousands of French seamen were made welcome and 15,000 booklets were distributed among them. Miss Weston received a warm vote of thanks from the men and a kind letter from Admiral Caillard, the French Commander-in-Chief. The circulation of *Ashore and Afloat* remains very large; the number issued during the year was 1,434,930, an increase of 42,750 over the previous year. A new wing has been added to the Portsmouth Royal Sailors' Rest, consisting of a small hall, club and class rooms, seamen's reading rooms, and a petty officers' coffee room, costing some £5000; this wing is just about to be opened by the Naval Commander-in-Chief, Admiral Sir Archibald Douglas. The number of men sleeping at the various Sailors' Rests during the year stands at 363,703. The number of baths given was 79,610 and of meals 677,137. The receipts were £30,977 2*s.* 4*d.* All the profits were, as usual, spent for the benefit of blue-jackets, their wives, and families. The quantity of meat consumed stands at 109,003 pounds, tea 6704 pounds, eggs 374,000, and milk 20,090 gallons. Miss Weston is raising the money for a Nelson Memorial block at Portsmouth, which she hopes to commence shortly, and so to add still more to the efficiency of her work at the premier naval port.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (3 P.M.).

TUESDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.).

WEDNESDAY (9th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan 9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.).

Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.).

FRIDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.) Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), St. Mark's (2.30 P.M.).

SATURDAY (12th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are *performed daily*.

SOCIETIES.

MONDAY (7th).—SOCIETY OF ENGINEERS (Royal United Service Institution, Whitehall).—7.30 P.M. Paper:—Dr. D. Sommerville: The Chemistry and Bacteriology of Potable Waters.

TUESDAY (8th).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. *Paper:—Dr. G. Rankin* and Dr. E. O. Mackay: Achondroplasia (with epidiascope demonstration).

MEDICO-LEGAL SOCIETY (22, Albemarle-street, W.).—8.15 P.M. Exhibition of Medico-legal *Specimens*. Discussion on Insanity and Murder (opened by Dr. O. Shaw). Mr. Justice Walton (President), Dr. H. Maudsley, Dr. T. S. Clouston, Dr. J. Scott, and Dr. Cowburn are expected to contribute.

WEDNESDAY (9th).—DERMATOLOGICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish square, W.).—5.15 P.M. Meeting.

SOCIETY OF ARTS (John-street, Adelphi, W.C.).—8 P.M. *Paper:*—Prof. T. Oliver: Bridge Building by means of Caissons, including *Remarks upon* Compressed Air Illness.

THURSDAY (10th).—HARVEIAN SOCIETY OF LONDON (Paddington Infirmary, Harrow road, W.).—8.30 P.M. Clinical Meeting. Cases will be shown.

BRITISH GYNÆCOLOGICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Paper:—Mrs Scharlieb: The Advantages of the Abdominal Route in Operations for Cancer of the Uterus.

FRIDAY (11th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Mr. C. Wallace: Case of Cystic Tumour of the Spermatic Cord.—Mr. A. C. Hudson: Carcinoma of the Thyroid Gland.—Mr E. W. Roughton: Case of Perforated Gastric Ulcer treated by Evisceration and Irrigation.—Mr J. D. Malcolm: Complete Removal of a Multilocular Cyst of the Pancreas; Intestinal Anastomosis for Partial Obstruction 16 Days later.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (7th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Dr. J. Galloway: Clinique. (Skin) 5.15 P.M. Lecture:—Dr. J. E. Squire: Bronchiectasis.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—12 noon. Dr. H. Wright: Pathological Demonstration. 2.15 P.M. Medical and Surgical Clinics. 3 P.M. Dr. Hood: Demonstration in Medical Wards. 5 P.M. Dr. Russell: Cerebral Hæmorrhage and Thrombosis.

CHARING CROSS HOSPITAL.—4 P.M. Dr. I. Bruce: Demonstration (Electrical) (Post Graduate Course.)

TUESDAY (8th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. G. A. Sutherland: Clinique. (Medical.) 5.15 P.M. Lecture:—Mr. H. J. Paterson: Gastric Ulcer.

POST GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—2.15 P.M. Medical and Surgical Clinics. 5 P.M. Dr. Russell: Cerebral Hæmorrhage and Thrombosis.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen square, Bloomsbury, W.C.).—3.30 P.M. Clinical Lecture:—Dr. Tooth: Neuritis.

NORTH EAST LONDON POST GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 P.M. Clinical Lecture:—Dr. H. Corner: Mental Affections of Childhood and Adolescence.

WEDNESDAY (9th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Mr. P. L. Daniel: Clinique. (Surgical) 5.15 P.M. Lecture:—Dr. G. H. Savage: Eccentricity and Insanity.

POST GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—2.15 P.M. Medical and Surgical Clinics. 5 P.M. Dr. Beddard: Practical Medicine.

UNIVERSITY COLLEGE HOSPITAL (Gower street, W.C.).—4 P.M. Clinical Lecture:—Dr R. Bucknall: The Diagnosis and Treatment of Tubercular Disease of the Spine.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn road, W.C.).—5 P.M. Demonstration:—Dr. D. Grant: Larynx.

THURSDAY (10th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical) 5.15 P.M. Lecture:—Mr C. Nourse: Some Points in the Diagnosis and Treatment of Frontal Sinusitis.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—2.15 P.M. Medical and Surgical Clinics. 4 P.M. Mr. Keetley: Demonstration in Surgical Wards. 5 P.M. Mr. Baldwin: Practical Surgery.

NORTH EAST LONDON POST GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 P.M. Lecture:—Dr. A. J. Whiting: Clinical Examination of the Blood.

CHARING CROSS HOSPITAL.—4 P.M. Mr. Wallis: Demonstration (Surgical).

FRIDAY (11th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies street, W.C.).—4 P.M. Mr. S. Stephenson: Clinique. (Eye)

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—2.15 P.M. Medical and Surgical Clinics. 3 P.M. Dr S. Taylor: Demonstration in Medical Wards. 5 P.M. Dr. Abraham: Cases of Skin Disease.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Clinical Lecture:—Dr R. Russell: Cerebral Tumours.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

The Goulstonian Lectures

ON

AUTO-INTOXICATION: ITS RELATION TO CERTAIN DISTURBANCES OF BLOOD PRESSURE.

Delivered before the Royal College of Physicians of London on March 13th, 15th, and 20th, 1906,

BY H. BATTY SHAW, M.D. LOND., F.R.C.P. LOND.,

LECTURER IN THERAPEUTICS, UNIVERSITY COLLEGE, LONDON; ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

LECTURE I.

Delivered on March 13th.

MR. PRESIDENT AND GENTLEMEN,—Before entering upon the discussion of the subject of auto-intoxication it is my duty to acknowledge the high compliment that has been paid to me by inviting me to deliver the Goulstonian lectures for the present year. Dr. Goulston was impressed with the importance of pathological study and sought to insure that lectures should be given annually by one of the four junior Fellows of this College on observations resulting from a close scrutiny of pathological problems. He thereby contributed his support to the wholesome belief that theoretical considerations should not be tolerated except when supported by direct observation. If during these lectures I confine myself largely to problems connected with proteid and nucleo-proteid reaction both in the natural and disintegrated state rather than to the study of carbohydrates and of hydrocarbons, an explanation is offered that only last year Dr. W. Cecil Bosanquet on a similar occasion to the present one drew attention to this most interesting side of the problem. If, again, the considerations to be put before you on the present occasion refer largely to matters connected with the disturbances of the circulation and the cardio-vascular mechanism, the reason offered is that during the last few years such important additions have been made to our methods of clinically investigating circulatory disorders, that it appears to your lecturer that the time is ripe for a consideration of some pathological problems which now have assumed a new aspect.

It is an experience common to us all that during our careers as physicians some one of the numerous problems brought to our notice at the bedside, post-mortem room, or laboratory has appealed to us with peculiar insistence. The following incident is a case in point.

A married woman, aged 48 years, was admitted to University College Hospital under the care of the late Dr. G. V. Poore. She was suffering from acute bronchitis and died a few minutes after admission. At the post-mortem examination, besides diffuse bronchitis and scattered patches of broncho-pneumonia, the following observations were made. The heart weighed 14 ounces, the left ventricle was hypertrophied, the mitral valves were sclerosed and incompetent, and the arch of the aorta showed atheroma. The right kidney was considerably enlarged and showed the scar of an infarct, its weight amounted to seven ounces; the left kidney showed extreme contraction and weighed 240 grains. The total kidney substance amounted to 213·95 grammes (the total kidney substance of an average adult male amounts to 277 grammes). The presence of an infarct scar in the right kidney suggested that a similar process accounted for the extreme shrinkage of the left kidney. To Dr. Harold S. Capper, house physician to Dr. Poore, was due the credit of making a close examination of the left renal artery. It admitted a fine bristle with difficulty; on carefully opening the renal artery a patch of atheroma was found which was responsible for the occlusion which had led to such a remarkable shrinkage of the left kidney.

Various points may be raised from a consideration of this case—e.g., on the share in the hypertrophy of the heart due to the mitral regurgitation and the share due to the practical annihilation of one kidney and the damage done to the other. Such questions in this case cannot be clearly answered, but another question arises and that is, Do we pay sufficient attention in the elucidation of various pathological problems to the grave results which may follow arterial disease? and a final problem is raised, What is the effect upon the economy when an organ such as the kidney disintegrates? It obviously must have disintegrated and the products of disintegration must have entered the circulation by the veins or lymphatics, and it is quite a subject for discussion to consider the possible effects of the presence in the circulation of such products of cell destruction.

No doubt the majority of diseases arise from external agencies but it is the object of these lectures to consider the possible effects due to auto-intoxication, to inquire into the changes which take place when from any other cause the organs and tissues of the body are made to disintegrate. Too large a field would lie before us if we attempted to discuss those auto-intoxications which result from the suppression of functions of various organs or from the internal diversion of natural excretions. Moreover, it is entirely beyond the scope of these lectures to discuss the so-called auto-intoxications which arise from infections occurring in the alimentary canal or other passages connected with the exterior. In other words, these lectures will to a certain extent concern themselves with very similar problems to those to which Gautier and Bouchard years ago addressed themselves. The term "leucomaines" was applied to three groups of bodies as represented by choline, uric acid, and creatinine. No doubt from a physiological point of view many of these leucomaines have in the past been regarded as very mildly toxic agents, but it is fair to assume with Pflüger that in pathological conditions, especially in cases where elimination is interfered with, the accumulation of the products of cellular disintegration, whether of a physiological or pathological origin, may have harmful effects.

At the present moment there are various reasons why pathology should be interrogated as to its answer to the question what symptoms and signs met with at the bedside may be attributed to auto intoxication in the above restricted sense. The principle is admitted most widely, but the exact evidence supporting such theory is, to say the least, not set out in our systems of medicine as clearly as the frequency with which we do not hesitate to invoke auto-intoxication demands. Another reason for discussing the problem is undoubtedly due to the fact that we are not able to trace directly to bacterial invasion some of the manifestations met with clinically: observers are quite sure that some effects are due to quite different causes than bacterial invasion. Toxins of cellular origin have been found to exist and brilliant discoveries have of late years been made in the domain of cytotoxins and of the interaction of organs derived from different animals upon one another. Such a subject, however, could not possibly form any part of a course of lectures on auto-intoxication. Much more excuse, however, is found for such lectures as the present one, on the grounds that in the domain of chemical physiology great advances have been made not only abroad but in this country. The reaction of derivatives of the disintegration of cells is a subject which appears, ever since the discoveries made by the late Dr. Wooldridge, to have excited particular interest in this country and in my endeavours to approach the subject of auto intoxication I find that his researches form the foundation of a great deal of modern chemical physiology and largely, I venture to think, because with such clear insight he saw what an immense importance such a subject has for pathology. If a large part of these lectures is devoted to the subject of blood pressure in disease, my excuse must be that the remarkably accurate estimate given by the sphygmomanometer of human blood pressure[1] has given such an impetus to the investigation of clinical blood pressure that we are flooded out with a large number of facts but are hardly able to appreciate their significance.

With this brief introduction I may pass on to the closer study of auto-intoxication—i.e., to the study of the effects of the dissolution of cells of various organs and tissues as shown by the toxic effects of their products, restricting myself in the main to the consideration of the products of proteid and nucleo-proteid degradation, including not only the deep degradation products but those more vital agencies a study of which is only possible when we examine the effects produced by fresh tissues—i.e., tissues which, though disintegrated by mechanical means, may be considered still living tissue in so far as the formation of their deep disintegration products has not yet begun.

BLOOD PRESSURE IN HEALTH AND DISEASE.

Very considerable interest has been aroused in recent years in the clinical observations of blood pressure. The range of variations in different diseases is considerable and great departures from the normal have been observed in various medical disorders. I propose to bring before you some observations made on patients under the care of my colleagues. Care has been taken to follow the precautions laid down by various writers on the subject. The observations were taken twice daily at about 9–10 A.M. and 8–10 P.M. In all cases, where possible, the patients were recumbent and the arm was so arranged that that part of the limb—viz., the upper arm—on which the sleeve of the sphygmomanometer was applied was on the level of the heart. In some cases recumbency was impossible: then the arm was raised by means of pillows so that the upper arm and heart were on the same level. The instrument used throughout has been the Riva-Rocci sphygmomanometer as modified by von Recklinghausen.[2] The latter observer discovered that the width of the armlet or manchette was of importance; if too narrow the pressure reading was considerably higher than if a wider armlet was used. The size of the sleeve which von Recklinghausen found to be the most satisfactory was for an average adult's arm 10 centimetres; a width of 15 centimetres was suitable for all sizes of arms. The armlet used in the present observations consisted of two parts, a rubber bag which was immediately applied to the arm and a metal band which encircled the bag; the former measured 13·97 centimetres and the latter 12 centimetres in width. The tubing was stiff rubber, outside diameter half an inch and diameter of bore three-sixteenths of an inch. As much precaution as possible was taken to prevent any excitement on the part of the patient when the reading was taken. The readings at night were in a large proportion of cases taken by members of the nursing staff of University College Hospital; in the mornings the observations were mostly personal ones. The blood pressure observations represent the systolic pressure, air being pumped into the hollow armlet until the pulse of the arm was obliterated and then observation was made of the height of a column of mercury in a manometer connected with the hollow armlet; that height was recorded at which the pulsation of the radial artery returned; the readings were repeated once or twice before being recorded and in many cases until accuracy was secured to the observer the observations were checked by another observer. In all cases, unless otherwise specified, there was complete absence of œdema or muscular rigidity.

Thayer[3] has constructed a table of the blood pressure in 276 healthy individuals arranged in decades. Making a correction of 25 millimetres for the use of a 5·0 centimetre armlet in the cases he observed after ten years of age, the variation is shown as in the accompanying chart.

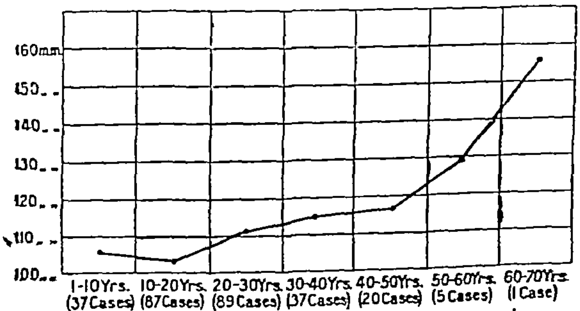

Diagram showing rise of systolic pressure with increasing years in healthy persons.

The rise of pressure in later years may be due to a variety of causes of pathological nature; the common visible accompaniments of advancing age—viz., arterio-sclerosis and cardiac hypertrophy—are well known, but as it is also known that old age may occur without these accompaniments, it must be felt that the rise of pressure so often met with in old age may be due to certain causes of which at present we are ignorant and which are of a pathological origin. Through the courtesy of Dr. Harley Brooks of the Mile End Infirmary it has been possible to add further observations on the blood pressure of elderly people. 23 men were examined between 10 A.M. and 12 noon and the blood pressures were taken in the manner already described. Two cases were observed at ages between 40 and 50 years; two between 50 and 60 years; seven between 60 and 70 years; four between 70 and 80 years; and eight between 80 and 90 years. The average pressure of the seven cases between 60 and 70 years was 155·8 millimetres, which agrees with the one case recorded in Thayer's chart; between 70 and 80 years the average pressure was 166 millimetres; and between 80 and 90 years 155·3 millimetres. Most of these patients were bed-ridden; the observations made are shown in Table I.

TABLE I.—*Systolic Blood Pressure in Infirmary Patients (Men in Recumbency).*

Case.	Age.	Systolic pressure.	Clinical association.
1	49	83 mm.	Tuberculosis; arterio-sclerosis; no albumin.
2	46	143 ,,	Ulcers of the legs; no arterio-sclerosis; no albumin.
3	55	138 ,,	Rheumatoid arthritis; slight albumin.
4	53	163 ,,	Sciatica; arterio-sclerosis; no albumin.
5	69	158 ,,	Ulcers of the legs; trace of albumin; very slight arterio-sclerosis.
6	67	170 ,, (left arm)	Right hemiplegia; arterio-sclerosis; some albumin.
7	65	110 mm.	Arterio-sclerosis; ? lymphadenoma; no albumin.
8	60+	160 ,,	Ununited fracture; no albumin.
9	65	160 ,,	Paralysis agitans; slight arterio-sclerosis; no albumin.
10	66	123 ,,	Bronchitis; moderate arterio-sclerosis; no albumin.
11	60+	210 ,, (right arm)	Left hemiplegia; marked arterio-sclerosis; albumin present.
12	76	180 mm.	Diarrhœa; moderate arterio-sclerosis.
13	72	194 ,, (left arm)	Partial right hemiplegia; trace of albumin.
14	78	155 mm.	Debility; arterio-sclerosis.
15	73	145 ,,	Ulcer of the leg; moderate arterio-sclerosis; albumin.
16	80+	155 ,,	Eczema; arterio-sclerosis.
17	82	144 ,,	"Senility"; albumin present; arterio-sclerosis.
18	88	130 ,,	Marked arterio-sclerosis; diarrhœa, "debility."
19	81	107 ,,	Marked arterio-sclerosis; ? cystitis.
20	80	175 ,,	Debility; arterio-sclerosis; no albumin.
21	86	190 ,,	Bronchitis; marked arterio-sclerosis; albumin.
22	83	182 ,,	"Debility"; arterio-sclerosis.
23	83	160 ,,	Bronchitis; arterio-sclerosis; albumin.

Three only of these cases show moderate pressure. Case 1, aged 49 years, showed a pressure of 88 *millimetres*; it will be noticed that he had tuberculosis of the lungs, a disease which is associated with low pressure. Case 7, aged 65 years, had a pressure of 110 millimetres; Case 10, aged 66 years, had a pressure of 123 millimetres; and Case 19, aged 81 years, had a pressure of 107 millimetres; in this latter case it is to be observed that the urine was offensive. Despite the want of uniformity in the readings of the sphygmomanometer these observations confirm the view that with increasing years there is generally a rise of arterial pressure. To mark the contrast between this hypertension of age and possibly disease with the pressure met with in an earlier period of life with health reference was made to the blood pressure of young healthy males in the persons of 42 schoolboys attending University College School. I take this opportunity to thank Dr. H. J. Spenser for his courtesy in allowing these observations to be made. These boys were so healthy that they were able to take part in gymnastic exercises. The time chosen for examination was between 10.30 A.M. and 12.40 P.M. The boys were immediately before examination engaged in class work, not in gymnastic exercises. The average blood pressure in recumbency of six boys between 11½ and 12½ years of age was 104·5 millimetres; between 12½ and 13½ years, 105·5 millimetres; between 13½ and 14½ years, 107·5 millimetres; between 14½ and 15½ years, 108·8 millimetres; between 15½ and 16½ years, 124·1 millimetres; between 16½ and 17½ years, 118·8 millimetres; and between 17½ and 18½ years, 111·6 millimetres. (Table II.)

---

12	$13\frac{6}{12}$	109 „	33	$16\frac{11}{12}$	105 „
13	$13\frac{8}{12}$	104 „	34	$17\frac{1}{12}$	122 „
14	$13\frac{10}{12}$	105 „	35	$17\frac{4}{12}$	152 „
15	$13\frac{11}{12}$	112 „	36	$17\frac{6}{12}$	113 „
16	$14\frac{3}{12}$	127 „	37	$17\frac{8}{12}$	98 „
17	$14\frac{4}{12}$	103 „	38	$17\frac{9}{12}$	109 „
18	$14\frac{5}{12}$	95 „	39	$17\frac{11}{12}$	128 „
19	$14\frac{10}{12}$	87 „	40	$18\frac{2}{12}$	93 „
20	15	127 „	41	$18\frac{3}{12}$	137 „
21	15	104 „	42	$18\frac{4}{12}$	105 „

Here, again, it is very obvious that there are variations in the systolic blood pressure of different individuals of the same age and from the above table it will be seen that there is no steady advance in pressure in accordance with the age of these youths; no doubt some of the pressures are unusually high and may be attributable to a little excitement on the part of the boys examined. Precautions were, however, taken to avoid these disturbances as much as possible, the pressure being first taken in the sitting posture to accustom them to the instrument and then after from three to four minutes' recumbency they were examined again and the above results obtained. It is well known that a very different reading is given after the same mental excitement in individuals of different temperament, being higher in the more excitable

BLOOD PRESSURE IN DISEASE.

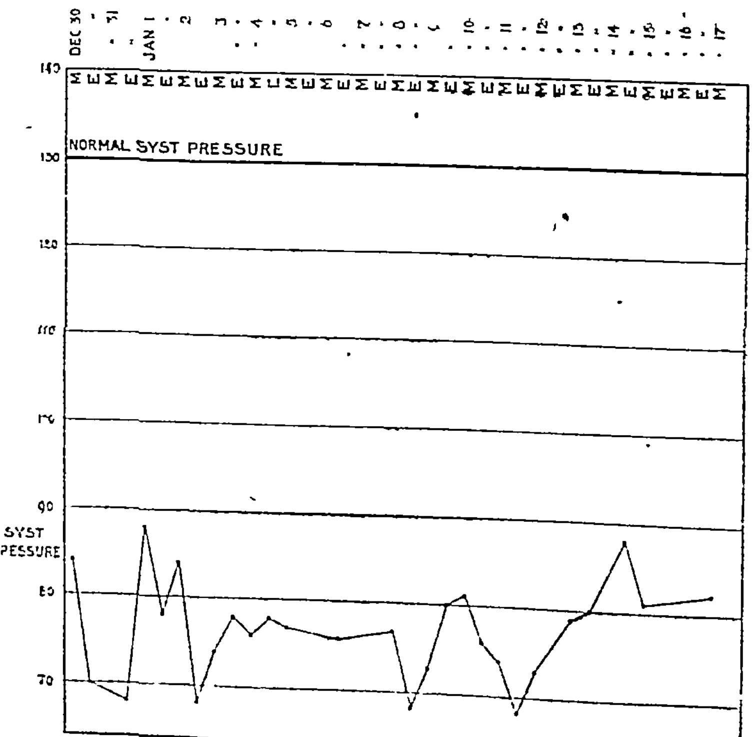
Janeway[4] states that in adult life the pressure is in men before 50 years of age from 100 to 130 millimetres and after 50 years from 130 to 145 millimetres, and in women about 10 millimetres less using the 12 centimetre armlet. Observations, 68 in number, have been made in various forms of disease in the wards of my colleagues at University College Hospital. Taking Janeway's figures as a guide, 42 cases were found to have systolic pressures within the limits of ordinary health, and these included under a clinical diagnosis: cirrhosis of the liver, four cases; valvular disease, eight cases; *diabetes mellitus, four cases; bronchitis* and emphysema, four cases; aneurysm and arterio-sclerosis, two cases; tuberculosis of the lungs, two cases; other diseases, 18 cases. (Under the last category are included dyspepsia, ascites following removal of ovarian tumour, meningitis, disseminated sclerosis, neurasthenia, gastric ulcer (two cases), gall-stones (without jaundice), tabes dorsalis (two cases), alcoholic neuritis, hæmaturia, acute rheumatism, otitis media, pernicious anæmia, exophthalmic goitre, lymphadenoma, and trypanosomiasis.

A second group of cases of *abnormal* blood pressure includes two subdivisions: 1. A number of cases in whom the blood pressure was *lower* than normal. They were 14 in number and included the following: acute bronchitis (fatal), arterio-sclerosis (? abdominal aneurysm), acute pneumonia, cirrhosis of the liver, advanced carcinoma of the stomach (two cases), jaundice (two cases), empyema, malaria, status epilepticus, chronic Bright's disease, aneurysm of the arch of the aorta, and a case of unusual character in which the only signs were pain about the root of the nose associated with a hard œdema of the neighbouring skin, independent of suppuration of the frontal sinuses, &c. (See Charts 1 and 2) 2. A number of cases in whom the blood pressure was *higher* than normal; these were 12 in number.

CASE 1.—A man, aged 80 years, was taken to the hospital shortly after an attack of giddiness and fainting which occurred whilst walking. He was found to be conscious but there was paresis of the left arm, leg and face. The pulse was 90, of large volume and of high tension. There were present marked arterial disease and an accentuated second aortic sound. The urine was reduced in amount, showed a specific gravity of 1018 and a cloud of albumin. The blood pressure is shown in Chart 3.

A post-mortem examination was made eight days after admission. There was no cerebral hæmorrhage: the arteries at the base of the brain were markedly atheromatous and dilated. There was no thrombosis in the larger cerebral vessels; the sinuses were normal; the convolutions were apparently normal. The heart weighed 16 ounces; the valves were normal. There was atheroma of the aorta, the limb-vessels, and the coronary arteries. With regard to

CHART 1.

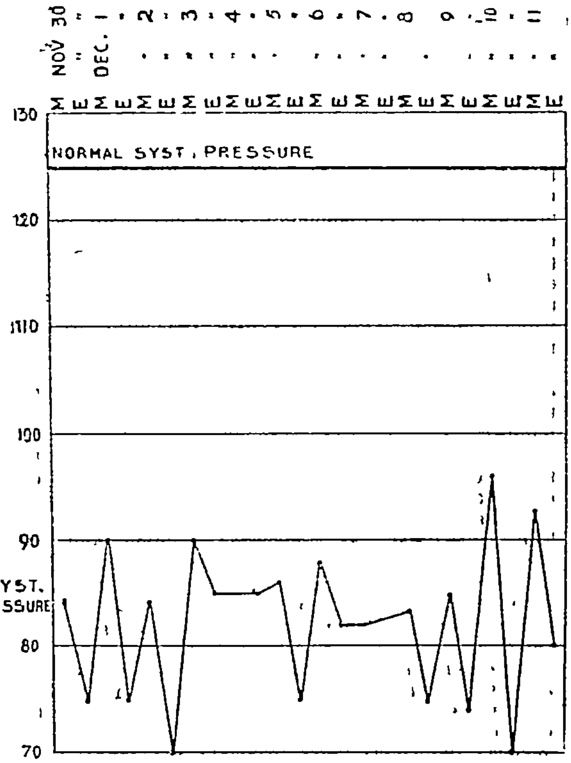


A man, aged 41 years, carcinoma ventriculi the kidneys, the right weighed four ounces and the left four ounces; the capsules were adherent; the cortex was reduced to one-eighth of an inch, the substance was tough, and cysts were present.

---

[4] Janeway: The Clinical Study of Blood Pressure, 1904.

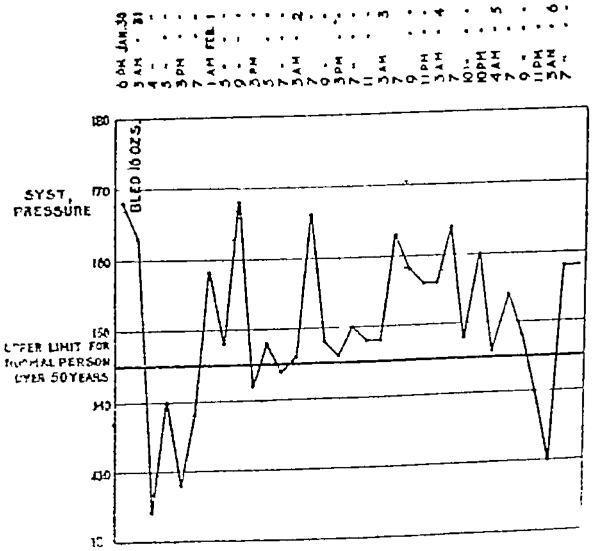
CHART 2.



A man, aged 35 years; œdema of the face.

CASE 2 (*vide* Chart 4).—A man, aged 41 years, was admitted for headache and hæmaturia. The patient was emphysematous and the body was well covered; no clinical signs of hypertrophy of the heart were present; there was slight tortuosity of the vessels. The quantity of urine varied from 20 to 58 ounces daily; it was of specific gravity 1010 to 1015 and contained albumin from 0·15 to 0·175 per cent.; it contained blood and a variety of casts. Œdema was slight and confined to the lower trunk and legs. The headache gradually disappeared and the hæmaturia became less. The patient was discharged at his own request; the albuminuria being still present; the œdema had disappeared.

CHART 3.

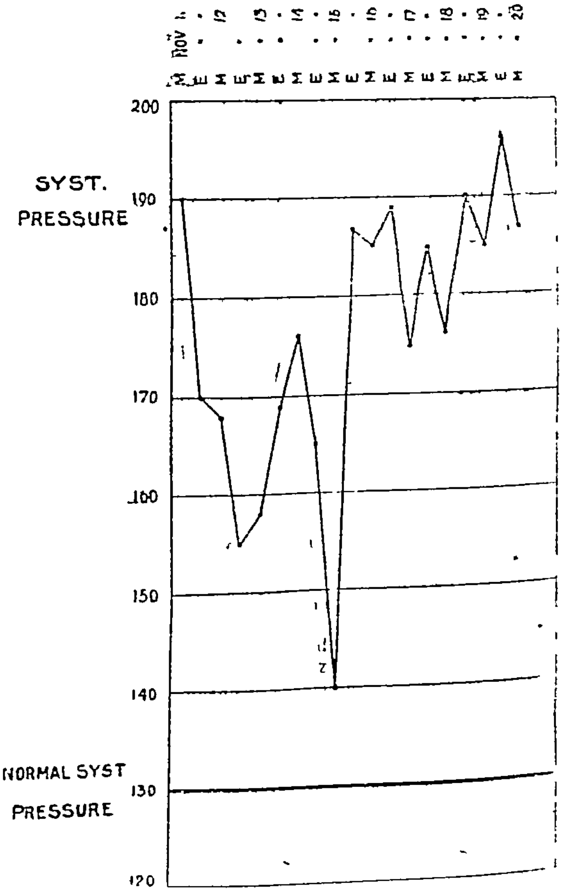


A man, aged 80 years, uræmia.

CASE 3 (*vide* Chart 5).—A lad, aged 17 years, was admitted for albuminuria and slight œdema of the legs He had had scarlet fever three years previously and six months later his legs began to swell and had remained swollen ever since. The first sound at the apex was booming in character and the aortic second sound was accentuated; the vessels of the arms were more rigid than usual. He passed from 22 to 70 ounces of urine daily; it was of specific gravity 1005 to 1015 and contained albumin from 0·16 to 0·3 per cent. He was discharged feeling much better and the dropsy had disappeared.

CASE 4.—A man, aged 69 years, was admitted for sensory aphasia of some months' duration; there was no associated hemiplegia. Rigidity of the vessels was very marked; the aortic second sound was accentuated and there was 0·1 per cent. of albumin in the urine; he passed from 26 to 53 ounces daily. The temperature was normal. His systolic blood pressure was constantly above 160 millimetres and reached as much as 184 millimetres. His only complaint was the aphasia and he was ultimately discharged.

CHART 4.

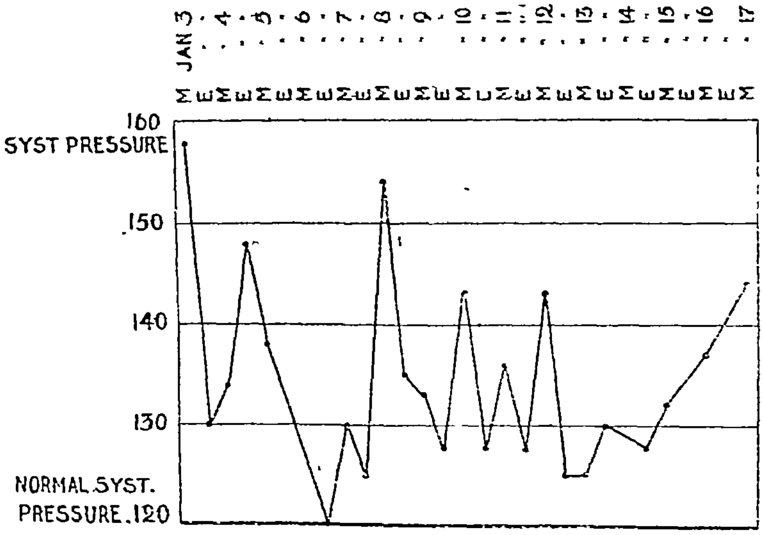


A man, aged 41 years; acute Bright's disease.

CASE 5.—A man, aged 21 years, was admitted for severe dyspnœa and orthopnœa; there was œdema of the lower extremities which increased till death supervened. The amount of urine passed varied from 30 to 70 ounces and gradually was diminished to 6 or 12 ounces; it was of specific gravity from 1010 to 1020; the albumin varied from 0·4 to 1·5 per cent. The blood-vessels were not abnormally tortuous or hardened; there was no marked accentuation of the aortic second sound; the temperature was normal. The blood pressure varied from 125 to 144 millimetres and towards the end underwent rapid diminution, becoming subnormal; the dyspnœa intensified till death.

At the post-mortem examination the heart was found to be greatly enlarged and dilated, weighing 19 ounces. The kidneys gave evidence of being much tougher than usual; they weighed seven ounces each.

CHART 5



A lad, aged 17 years, chronic Bright's disease (? contracted kidney)

CASE 6.—A man, aged 43 years, was admitted suffering from uræmia. He was dyspnœic and had a pulse-rate of from 23 to 34 beats per minute; the temperature was normal. The brachial blood-vessels were markedly thickened and tortuous. Only 20 ounces of urine were passed during the 25 hours he survived. It was loaded with albumin and casts were abundant. Five blood pressure observations showed 160, 140, 162, 163 millimetres, and the last taken at 12 midday was 160 millimetres. At 1 o'clock the pulse could not be felt and at 1 30 P M the patient died.

At the post-mortem examination the heart weighed 27 ounces; the left ventricle especially was greatly dilated and hypertrophied; the coronary arteries and aorta were atheromatous and the limb vessels were thickened. The kidneys weighed six ounces each, the capsule stripped off readily; the cortex was one eighth of an inch in depth; the renal arteries were thickened and atheromatous.

CASE 7.—A man, aged 32 years, was admitted with uræmic dyspnœa and almost complete suppression of urine—only four ounces in two days. Albumin, blood, and casts were present in the urine and the patient was slightly œdematous in the lower extremities, had diarrhœa and sickness, and there was also some fever. The maximum impulse of the heart was in the fifth space, external to the nipple line; the second aortic sound was accentuated. Four observations were made on the blood pressure: Oct. 30th, evening, 187 millimetres; Oct. 31st, morning, 167 millimetres; evening, 162 millimetres; and Nov. 1st, at 10 A M, 88 millimetres. Death occurred seven hours later.

At the post-mortem examination the kidneys were found to be red, granular, and contracted, and contained cysts; the cortex was greatly reduced; each kidney weighed four ounces; the renal vessels were narrowed. The heart weighed 14 ounces; the coronary arteries were fairly healthy; there was very little atheroma in the aorta or vessels of the limbs.

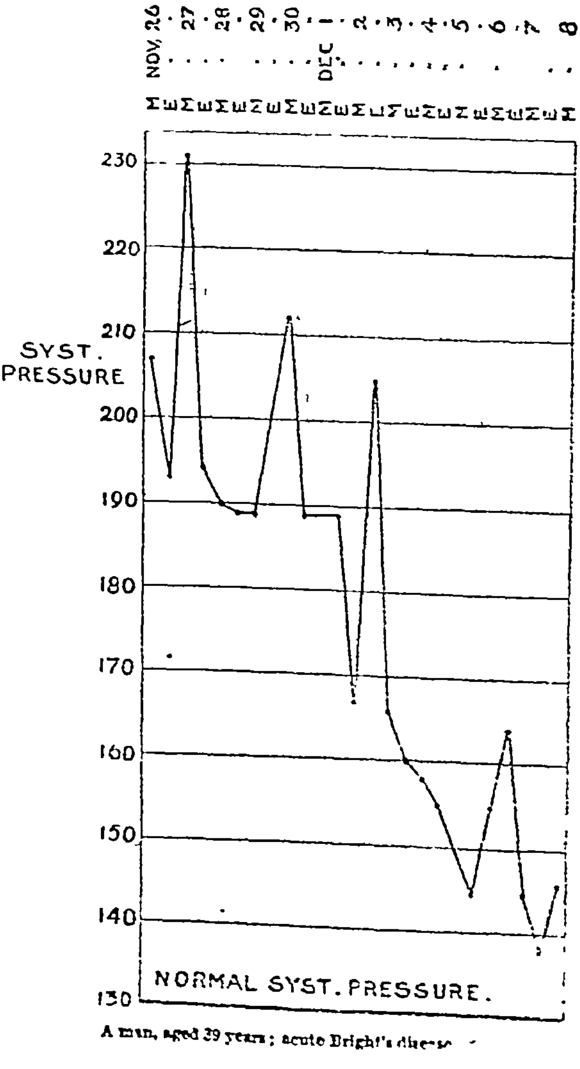
CASE 8 (*vide* Chart 6).—The patient was a man, aged 39 years. He was admitted for headache and sickness; he had also had puffiness of the feet for three weeks. The urine was albuminous but there was no sign of arterial disease and the heart revealed no signs of hypertrophy. The temperature was normal. The symptoms gradually abated and he was discharged. The chart shows the elevation and gradual fall of the blood pressure in acute Bright's disease.

CASE 9 (*vide* Chart 7).—A married woman, aged 41 years, was admitted for headache, œdema of the ankles, and albuminuria. There were no signs of cardio-vascular disease. There was some fever. The urine varied from 15 to 43 ounces daily; it was of specific gravity from 1013 to 1028. Albumin varied from 0 12 to 0·20 per cent. The blood pressure varied, falling during her stay in the hospital but rising above normal again prior to her discharge.

CASE 10 (*vide* Chart 8).—A man, aged 43 years, was admitted for pains in the chest and headache and for some dropsy in the feet. He had had a similar illness three years previously and had passed blood in his urine. There were no marked changes in the cardio-vascular system. The urine varied from 47 to 92 ounces; on three days it was, however, much less—10, 20, and 18 ounces respectively; it was of specific gravity from 1010 to 1027. On admission he was passing 0·33 per cent. of albumin but on his discharge there was only a trace; blood was passed on several occasions. There was a copious deposit of casts on admission. He developed severe uræmia with convulsions and was bled and infused. He left the hospital quite free from symptoms.

CASE 11 (*vide* Chart 9).—A man, aged 55 years, was admitted for extensive lead palsy and was found to have a blood pressure which ranged from 155 to 177 millimetres. This gradually subsided to normal. The arteries were very tortuous and the second aortic sound was accentuated; the maximum impulse of the heart was obscured by emphysema. The specific gravity of the urine was from 1015 to 1022; a slight trace of albumin was present. He was discharged relieved to a certain extent.

CHART 6.



A man, aged 39 years; acute Bright's disease

Schryver, who pointed out to me a certain period subsequent to the removal of tissues from animals in which the tissues do not undergo chemical change. An appeal, therefore, was made to the effects of fresh tissues removed from a cat and after preparation injected into another.

Mode of preparation.—An animal was killed under an anæsthetic and with aseptic precautions the liver, the kidneys, the brain, the spleen, &c., were removed. The kidneys were stripped of their capsules, then split, and as much as possible of the pelvis and the neighbouring vessels were removed; the bile duct and gall-bladder were cut away from the liver and all the organs were washed in sterile saline solution. So much of each organ was weighed out in grammes and to it were added three times the number of cubic centimetres of sterilised salt solution; this was then ground up with a small quantity of white sand which had been sterilised and washed in saline solution. After the preparation was thoroughly macerated it was pressed through fine meshed sieves, thus completing the disintegration of the organ. The preparation was then centrifugalised and filtered through coarse filter paper. The filtrate now took the form of a fine emulsion and showed microscopically many fine granules of varying size. The preparations were injected into other cats, as a rule from within two to four hours, and in one case not for 12 hours, the preparation having been kept in an ice-box at from 6° to 10° C. The anæsthetic used was ether in every case and care was taken without the aid of morphine or curari to secure deep anæsthesia. The ether was administered through a cannula inserted in the trachea in the latter part of each experiment. The blood pressure was recorded from the right carotid artery. A cannula was tied into the right femoral vein for the purpose of injecting the extracts.

TABLE IV.—SHOWING PRESSOR OR DEPRESSOR EFFECTS FOLLOWING INTRAVENOUS INJECTIONS OF EXTRACTS OF FRESH ORGANS.

No. of experiment.	Date.	Weight of kymograph animal in grammes.	Weight of animal from which organs were removed.	Anæsthetic, &c.	Nature of extract.	Amount and order of injection of extract of different organs.	c.cm.	Average maximum pressure immediately before injection. mm.	Effect on pressure. Rise (+) or fall (−) in millimetres of mercury. In Experiment 29 reference is made to the effects of normal kidney and to sclerosed kidney. This interesting condition is comparable to the specimens referred to in the beginning of the lecture in which one kidney was found to be atrophied as a result of atheroma of the renal artery, the other kidney being much larger than normal. In the case of the cat, the renal artery of the scarred organ was found to be much smaller than that of the healthy kidney.

The first series of experiments carried out in the above way included those animals in which several different tissue extracts were injected into the same animal; the order of injection is given in Table IV.; the series consisted of eight experiments carried out on eight animals—Nos. 12, 22, 23, 25, 29, 31, 32, and 33 A. No records of the experiments Nos. 12 and 23 are given; No. 12 was a curious example in which the animal failed to show any reaction—pressor or depressor—on the injection of any tissue or of saline solution alone. No. 23 was an example of an animal in whom the respiration was so irregular, quite apart from injection of material, that no attempt was made to carry out complete experiments. There are therefore six experiments left for consideration. The effects of injection of different organs upon the blood pressure have been tabulated and the analysis of the spleen and muscle effects shows that injection of spleen gave a rise of pressure on three occasions of 18 millimetres, two millimetres, and three millimetres, lasting respectively 45 seconds, 10 seconds, and 30 seconds; a fall occurred in two cases of four millimetres, lasting from one to two seconds, and of 6 millimetres, lasting four seconds. Injection of muscle extract was practised twice; in one there was a marked fall of 38 millimetres lasting four minutes 28 seconds, and in the other a fall of only four millimetres, lasting one minute 55 seconds. The observations on the kidney, the liver, and the brain were more numerous and are tabulated according to whether they caused a rise or fall (Tables V. and VI.).

In Tables V and VI. the heading "Maximum" means the highest or lowest maximum point the blood pressure reached respectively during the interval in which rise or fall occurred. The duration in Table IX. is qualified in many cases by the words "at least" because it was necessary in these cases to stop the kymograph and so economise tracing paper in order to get the whole series on one tracing.

It is obvious that though other organs than the kidney occasionally show a rise of pressure on injection, yet the rise is small and of short duration; whereas the kidney effect of a rise, though varying within considerable limits, is a striking feature, and the same may be said of the duration in which such rise takes place; no other organ has been noticed to have such an effect so frequently. The liver and brain show a much greater tendency to cause a fall of blood pressure and even then such fall is generally of very brief duration. One point to which it is necessary to draw attention is that in none of these experiments was the kidney extract injected first; the injection always succeeded that of some other organ and it may be objected that it is possible that the rise of pressure following the injection of renal extract is due to some interaction of renal extract with some previous extract. Moreover, it may be thought that the renal extract is of a different physical character and likely to cause a rise of pressure from some mechanical effect dependent upon the granules contained in the emulsion. As will be seen later, there is no reason to believe that either of these objections holds good. It is to be observed once again that these animals were simply under the influence of ether; this was so carefully administered that the respiration was maintained regularly. In another experiment, 33B, with ether anæsthesia and artificial respiration, the vagi were cut; an injection of renal extract then produced the exceedingly small rise of only four or one millimetre, lasting one minute 40 seconds and 25 seconds respectively. So far as this one experiment is concerned it must be stated that the second injection of an extract has on other occasions shown a less marked reaction than the first one. The slight rise, such as it is, merely suggests that the rise of pressure on injecting renal extract is due to a peripheral effect whereby the arterial pressure is raised.

A CASE OF

PRIMARY INTESTINAL ANTHRAX IN MAN; SEPTICÆMIA; HÆMORRHAGIC LEPTO-MENINGITIS.[1]

BY JOHN H. TEACHER, M.D. GLASG., F.F.P.S. GLASG.,
ASSISTANT TO PROFESSOR OF PATHOLOGY, UNIVERSITY OF GLASGOW, ASSISTANT PATHOLOGIST AT THE WESTERN INFIRMARY, GLASGOW.

THE following case of anthrax is of interest from several points of view. It appears to be an example of that form of the disease which is the most common in animals but the rarest in man—viz., that in which infection occurs through the alimentary canal. The infection was extremely virulent and the course of the disease was correspondingly rapid, the whole known duration of the illness being 20 hours. There was nothing in connexion with the occupation of the patient to suggest anthrax and the symptoms gave no clue to the nature of the disease Until the hæmorrhagic condition of the meninges was revealed at the post-mortem examination anthrax was never suspected. Moreover, the case appears to have been completely isolated and all investigations subsequently undertaken have failed either to reveal the source of the infection or to bring to light other cases of the disease in man or animals in the neighbourhood of the present one.

Clinical history by DR. ROBERT BELL.—A man, aged 36 years, was admitted to Ward 12 of the Western Infirmary, Glasgow, at 11.15 P.M. on Jan. 31st, 1905, in a semi-conscious and delirious state. According to the account of his friends he was to all appearance in perfect health until the morning of the day of his admission, when he rose with the intention of going to work but returned to bed because he felt giddy and had a headache. The headache he described as a pain beginning behind and shooting over to the forehead, while occasionally he complained of pain in the region of his right ear and right eye. He remained in bed all day and took a little light food, and he appeared to be not at all seriously ill. About 7 P.M., however, his friends heard him give a cry and went to the bed room, where they found him out of bed, very restless and excited, and talking in an unintelligible manner. He would not reply to any questions but would rise suddenly, go and sit down by the fire, holding his head and moaning, and then as suddenly he would jump into his bed again and would lie huddled up. This restlessness and excitement he showed in an increasing degree up to the time of his admission. The patient worked at the making of white lead in a paint manufactory. The people with whom he lodged had known him for five years and he had been an exceptionally strong and healthy man. They stated that he had not been a heavy drinker but he occasionally had a bout of two or three days' duration, after which he would be steady for some weeks When seen in the receiving room at 11.5 P.M. he was being held in a chair by three or four men so violent were his struggles. On admission to Ward 12 he seemed unconscious but if spoken to loudly he opened his eyes and looked about. If left to himself he lay huddled up with his legs and knees drawn tightly up and flexed upon the abdomen, his arms thrown across the chest, and his head bent with the chin on the sternum. But if any attempt were made to move him or rouse him he struggled violently and occasionally gave a low sighing moan. The pupils were moderately dilated and reacted sluggishly to light; they were equal. The teeth were tightly closed and could not be opened. On the gums there seemed to be a suspicion of a blue line. Respiration was easy and quiet, 24 per minute. The pulse was small, wiry, 90 per minute. The temperature was 98·4° F.

---

[1] Communicated to the Glasgow Pathological and Clinical Society in March, 1905.

Physical examination was difficult owing to the struggles of the patient on any attempt being made to move him. The knee-jerks could not be elicited and neither paralysis nor paresis was anywhere discovered. Examination of the lungs, the heart, and the abdomen revealed little except that he winced when comparatively slight pressure was made over the epigastrium and in the region of the umbilicus. There was no abdominal distension. No discharge was present from the ears or nose and there was no sign of conjunctival hæmorrhage. There was no evidence of injury of any kind. At 3 P.M. on Feb. 1st he began to have convulsions. The face was first thrown into contortions—both sides apparently equally. These then passed to the left arm, then to the left leg, and rapidly became general. In the convulsions the pupils became somewhat dilated. The urine drawn off by catheter was of specific gravity 1042 and contained sugar—a distinct reaction being obtained with Fehling's solution—and a considerable quantity of albumin. Four convulsive seizures occurred before death, the interval between successive seizures being short. In the last the pupils became contracted and fixed and the patient died immediately the convulsion ceased at 3.30 P.M.

Post-mortem examination.—This was made 31 hours after death. The body was that of a strongly built muscular man. Rigor mortis was well developed. The face and neck and posterior parts of the body showed considerable lividity. There was no external mark of injury or disease. As regards the thorax the mediastinal connective tissues were very œdematous. In the anterior mediastinum, just above the pericardium, there was a large and soft lymphatic gland. In section this was seen to be inflamed with hæmorrhages here and there; it showed a moderate degree of carbonaceous pigmentation. Other mediastinal glands behind this were noticed to be fairly large and hæmorrhagic. The heart was very flaccid and the muscle was soft and pale in colour. There was a considerable amount of blood-staining under the endocardium. There was no valvular lesion or defect. Each pleural cavity contained about ten ounces of clear serous (not bloody) fluid. The lungs were free from pleural adhesions; there was no condition of the lung substance which calls for note. The mucous membrane of the larynx, trachea, and large bronchi was intensely congested but no swelling, ulcerations, or hæmorrhagic patches were found. The tongue, the fauces, and the œsophagus were also very congested and the papillæ and masses of lymphoid tissue about the root of the tongue were swollen, but there were no hæmorrhagic patches and no erosions. The peritoneal cavity contained about ten ounces of yellowish turbid fluid. There was little appearance of general acute peritonitis but there was some dulness of the surface of the intestine here and there and several small hæmorrhagic areas in the small intestine. The largest of these was situated about four feet from the pylorus; it lay for the most part to one side of the mesenteric attachment; its deep red surface was flecked with yellow fibrinous material, and it appeared to be the centre from which an early acute general peritonitis was arising. The intestines as a whole were œdematous. Internally corresponding to the hæmorrhagic patches noted externally were hæmorrhagic areas surrounded by zones of intense congestion. The largest of these, corresponding to the principal lesion above described, was ulcerated in the centre. It was extensively infiltrated with blood but presented no feature by which it could be specifically designated, having, for example, no resemblance to a typhoid lesion; it was of quite recent acute character. This lesion measured about five centimetres in diameter and faded off gradually into the surrounding pale, œdematous mucous membrane. The central parts were almost black from extravasation of blood and in the very centre, just to one side of the mesenteric attachment, the intestinal wall appeared to be necrotic and on the point of perforation. A streak of intense congestion, studded with swollen, hæmorrhagic, lymphatic glands, extended from this to the root of the mesentery. Lower down were several smaller patches of similar character. The central spot in them had the appearance of a minute abscess but on cutting with the point of the knife it appeared to be a small slough with thick purulent fluid round about it. There was scarcely any alteration of the mesentery in the neighbourhood of these smaller lesions. The stomach was congested and near the pylorus were three small hæmorrhagic patches with rather elevated pustule-like centres about three millimetres in diameter. The liver weighed 65 ounces. It was very soft and pale from cloudy swelling. The spleen was considerably enlarged, very soft, and congested; it appeared to be septic in character. All details of structure in the pulp were blotted out and it flowed out in the form of a thick chocolate-coloured liquid. The kidneys were rather small but without irregularity of the surface; the cortex was thin and it was pale from cloudy swelling. As regards the head the dura mater was of normal appearance. The superior longitudinal sinus was empty of blood; it contained no thrombi. The cerebral hemispheres on both sides showed extensive and diffuse pia-arachnoid hæmorrhage. This was most marked over the vertex and rather more on the left than on the right side. There was also much blood over the surface of the cerebellum. On the lower surface of the cerebrum some hæmorrhage was present but very much less than over the vertex. There was also blood in small amount over the pons Varolii, medulla oblongata, and upper part of the spinal cord. The ventricles contained no abnormal amount of fluid; the choroid plexuses showed no hæmorrhage. The substance of the brain presented no abnormality but in the sulci of the cerebrum and cerebellum there was hæmorrhage, just as in the pia-arachnoid of the surface. The layer of blood, even where most abundant, was quite thin, the convolutions shining out quite clearly through it between the blood-filled sulci.

Up to the opening of the dura mater the case presented the appearance of some acute septic condition, to the exact nature of which there was as yet no clue. There was no evidence in favour of traumatic origin of the pia-arachnoid hæmorrhage. Professor R. Muir, who made the examination, considered the case to be one of septicæmia and asked me to examine the meningeal fluid. Having previously known of the association of meningeal hæmorrhage with anthrax I mentioned that it might be of this nature and this surmise was confirmed by my microscopical examination. The case was then treated as one of anthrax and precautions were taken to prevent infection of the staff and students who were attending the demonstration. The city sanitary authorities also received notification. Dr. A. K. Chalmers, medical officer of health of the city of Glasgow, placed the case in the hands of Dr. J. R. Currie, who made a thorough investigation of all the circumstances of the occupation, surroundings, and recent movements of the patient. Dr. R. M. Buchanan, city bacteriologist, made bacteriological examinations of all materials which might have carried infection, including bedding, clothing, handkerchiefs, and the tallow, waste, linseed oil, and tan used in his work, all with negative results. Trade and the ordinary casual sources of infection appeared to be excluded.

The nature of the case naturally directed attention to the possibility of food infection and milk and meat of which he was known to have partaken were examined and traced to farms or the meat market. No cases of anthrax could be traced at any of the farms but on one farm from which sheep were supplied several animals had recently died from some unnamed disease. All the carcasses to which suspicion could be attached had been passed by the inspector. In the opinion of Dr. Currie, the exclusion of other sources of infection, however, gives a certain degree of probability to the belief that an anthrax-containing carcass had been used for food in Glasgow at the time when this man contracted his fatal illness. Suspicion was directed to steak and to a pie of which he was known to have partaken along with others who did not suffer, but no sure evidence of infection could be obtained. There are many examples of anthrax carcasses having been consumed without a single case resulting. The organisms in the interior of meat are in the form of the bacilli which would in all probability be destroyed by the gastric juice. Spores, on the other hand, would escape destruction in the stomach, and it is most probable that the patient in this case had swallowed a dose of spores. The formation of spores might occur on meat which had lain for some time after being cut and imperfect cooking of such meat would permit their survival.

Film preparations from various organs were made and stained with thionin blue and by Gram's method. The fluid from the meninges contained, besides the red blood corpuscles and polymorpho- and mono-nuclear cells, large numbers of organisms having the morphological characters and staining properties of anthrax bacilli, diplococci, which were occasionally arranged in short chains, long thin bacilli and short bacilli with polar staining, the last two being Gram-negative organisms. Anthrax bacilli were not found in the film prepared from the mediastinal glands at first, but six hours later the fluid which had exuded from them was examined and was then found to contain numerous anthrax bacilli. Anthrax bacilli were also found in the films from the spleen, mesenteric gland, and intestinal lesion, as a rule accompanied by diplococci and streptococci. There was no trace of spore formation. The peritoneal exudate from near the largest intestinal lesion consisted of polymorphonuclear leucocytes and shed endothelium; it contained numerous streptococci but anthrax bacilli were not found. Apparently the lesion was virtually a perforation through which streptococci had reached the peritoneal cavity but not anthrax bacilli.

Cultures on agar and gelatin were made from the fluid in the meninges over the upper surface of the cerebrum and from the spleen. From the former were isolated the anthrax bacillus, diplococci resembling the pneumococcus, streptococci, a bacillus of the bacillus coli communis group, and an organism of about the same size, of oval form, showing distinct polar staining with thionin blue and decolourising by Gram's method. From the spleen the bacillus of anthrax, diplococci, and streptococci were obtained. Pure cultures were obtained of all but the organism with the polar staining. This was clearly not anaerobic as it was recognised in plate culture, but the agar-slope culture supposed to be taken from the colony grew only an organism resembling bacillus coli communis. The anthrax bacillus was submitted to the usual tests and gave quite characteristic growths in the different media.

The bloody fluid from the meninges diluted with sterile saline solution was injected in the skin of the abdomen of two guinea-pigs and into the auricular vein of a rabbit. 18 hours later the guinea-pigs were still fairly lively although undoubtedly ill, and the first died 21 hours after receiving the injection. There was some œdema without hæmorrhage around the seat of injection. The fluid contained swarms of diplococci with capsules and a certain number of anthrax bacilli. The peritoneal cavity contained a large amount of clear fluid in which were found a few mononuclear cells and large numbers of anthrax bacilli. The heart blood contained a few anthrax bacilli; the spleen contained anthrax bacilli and diplococci. The second guinea pig died four hours later. Round the seat of injection there were very marked œdema and hæmorrhage. Films contained some diplococci, a fair number of anthrax bacilli, and immense numbers of oval bacilli with distinct polar staining like the plague bacillus. No organisms were found in the blood or peritoneal fluid. The internal organs in general appeared healthy. Again the organism with polar staining was not isolated, the cultures yielding only the anthrax bacillus, cocci, and an organism of the colon group. The rabbit appeared fairly well at the end of the third day, but on the following morning it was found dead although still warm. The blood contained anthrax bacilli in considerable numbers and a few diplococci like pneumococci, and the organs swarmed with anthrax bacilli. Cultures yielded only anthrax. A third guinea-pig was inoculated from a subculture of this and it died from characteristic anthrax septicæmia in about 30 hours and pure cultures of the bacillus were recovered from the blood. Guinea-pigs were also inoculated with cultures of the streptococci from the spleen and diplococci from the meninges, but these hardly produced even a local reaction. It is therefore clear that the infection was true anthrax of a very virulent type and that while other organisms were present the anthrax bacilli were the principal pathogenic agents. The peritonitis in the patient demonstrated that the streptococci possessed some virulence and it appears probable that the other organisms also had pathogenic properties, the extraordinary numbers of the oval organism in the subcutaneous tissue of the second guinea-pig, which died without blood infection, being very suggestive as regards that particular organism.

Histology.—Sections were prepared from the stomach, intestines, spleen, mediastinal and mesenteric lymph glands, kidney, cerebrum, cerebellum, and root of the tongue. Unfortunately the liver and lungs were removed before portions had been taken for microscopical examination and could not be recovered. The microscopical examination confirmed the impression that the large lesion of the intestine above described was the principal seat of infection. The smaller spots in the intestine presented the character of small pustules, with necrosis of a central area from three to five millimetres in diameter involving little more than the mucous membrane and resting on a bed of polymorphonuclear leucocytes, which infiltrated the submucous and muscular coats throughout a relatively wide area. Wherever the leucocytes were found there were also anthrax bacilli in considerable numbers. The surface of the sloughing centre was crusted with organisms of various kinds. The large lesions presented a more advanced stage of a similar condition. The area of necrosis of the mucous membrane was quite small and infiltration of this coat by leucocytes or anthrax bacilli was confined practically to the necrotic centre, but intense congestion with more or less extravasation of blood was observed throughout a wide area round about it. The necrotic patches were situated on the edge of the valvulæ conniventes. The infective process, on the other hand, had spread widely in the submucous tissues and in the planes of tissue between the muscle bundles through to the subperitoneal layer. The peritoneal membrane was very ill defined in the sections. There had clearly been emigration of leucocytes beyond it and while no anthrax bacilli were recognised in the peritoneal exudate either in films or sections, streptococci were found in it in abundance and the anthrax organisms were seen in the subperitoneal tissue. This was the case even in the smaller lesions, which appeared to be nearing perforation, while the larger was in effect a perforation. The intestinal wall was swollen and its tissues were opened up by extravasation of blood and accumulation of leucocytes and necrosis of considerable extent had taken place. In the necrosed tissues very little could be made out of tissues or organisms, but in the surrounding tissues there was great accumulation of anthrax and other organisms. No anthrax bacilli had been observed within the blood-vessels in the wall of the intestines or in the vessels of the adjacent mesentery. The blood-vessels were so distended and packed with blood as to convey the impression that stasis of the circulation had occurred, but there was, as a rule, no sign of actual thrombosis within them. The walls of the vessels had a swollen hyaline appearance and the nuclei appeared to be reduced in number and stained badly as if they had been undergoing necrosis.

The sections of mesentery were taken from the part related to the largest lesion but beyond the first line of lymphatic glands. In them it was found to be deeply congested and swollen, its tissues extremely œdematous, hyaline, and breaking down in parts and infiltrated with enormous numbers of polymorphonuclear leucocytes, among which anthrax bacilli were found in small numbers. The mesenteric glands, even to the root of the mesentery, were swollen, necrotic in parts, and infiltrated with blood and polymorphonuclear leucocytes to an extent which obscures their proper structure. Anthrax bacilli were present in immense numbers, especially near the capsule, along with other organisms, of which streptococci were the most numerous.

The lesions in the stomach proved to be very small aggregations of leucocytes lying for the most part deep in the mucosa, surrounded by a zone of congestion. Anthrax bacilli, however, were found in them in considerable number. The spleen was so much distended with blood and polymorphonuclear leucocytes that the normal structure was hardly recognisable. The fine trabecular tissue of the pulp and the walls of small vessels were hyaline or broken down and the endothelium was shed and lay mixed with the blood and other cells. The Malpighian bodies could hardly be distinguished, the lymphoid tissue being for the most part replaced by large round cells with large vesicular nuclei and polymorphonuclear leucocytes clustering around the vessel. Phagocytosis by the large cells was not made out. Anthrax bacilli were present in considerable numbers in the blood and among the cells, and there were also some streptococci, as a rule in colonies. The swollen root of the tongue showed great congestion and a few streptococci in the lymphoid follicles but no anthrax bacilli. Several of these, however, were found in the widely dilated blood-vessels.

The supposed large mediastinal gland proved on section to be a mass of glands bound together by œdematous, blood-infiltrated, areolar and adipose tissues. The lymphatic and other tissues were overrun with polymorphonuclear leucocytes and broken up by hæmorrhage. Patches of necrosis were seen in all the tissues. Anthrax bacilli were found with difficulty but streptococci were present in large numbers, many of them occupying dilated blood-vessels. There was also much carbonaceous pigment, indicating that it lay in the drainage system of the lungs. In view of the loss of the lungs this condition is of importance, the contrast between these glands and the mesenteric glands in respect to the presence of anthrax bacilli confirming the naked-eye impression that the lungs and bronchi were free from primary anthrax lesion.

The kidneys, in spite of their comparatively normal appearance to the naked eye, were the seat of most profound changes. The epithelium of the convoluted tubules was entirely necrotic and so swollen as to occupy practically the whole lumen of the tubules; that of the straight tubules was more or less swollen and shed but not necrotic. Many of the basement membranes were swollen and hyaline. The glomeruli presented no sign of the acute disease beyond some hyaline change. A very few anthrax bacilli were found in them and in blood-vessels. There was distinct evidence of an old interstitial nephritis in increase of connective tissue and some sclerosis of glomeruli. The blood-vessels, especially in the pyramids, were distended with blood and there was a little extravasation in places.

The sections of the brain showed that the hæmorrhage had occurred in the pia arachnoid. There was for the most part no layer of blood such as has been described in cases of longer duration and was seen by me in sections from a case in Vienna, but the whole thickness of the pia-arachnoid was more or less opened up by the escaped blood which occupied its interstices and also in places separated its deep surface from the brain. In some sections, however, the layer of blood was thicker and more homogeneous. Over the convolutions *the pia-arachnoid was only from a quarter to* one millimetre thick, but the quantity of effused blood was greater in the sulci. To the naked eye the subdural space appeared quite free from blood, but in some parts of the sections a layer of leucocytes mixed with some red corpuscles was found lying apparently on the surface of the pia-arachnoid. The inflammatory character of this exudate was of interest because in many parts of the pia-arachnoid the condition had the character of a diffuse hæmorrhage rather than a hæmorrhagic meningitis, the polymorphonuclear leucocytes and free-lying mononuclear cells being scarcely more numerous in the extravasated blood than in that within the vessels, and there being no leucocytic exudation in the tissues There were, however, some masses of older blood clot and thrombus with fibrin network in which polymorphonuclear leucocytes were present in large numbers. In places, also, one found considerable collections of polymorphonuclear leucocytes in the pia-arachnoid, especially in its deepest layer. The anthrax bacilli were found in very small numbers in the exudate on the free surface of the pia-arachnoid but in immense numbers within that membrane. They were perhaps most numerous in the leucocyte-infiltrated tissues and in the older masses of blood, but they were also present in large numbers in areas of connective tissue which showed no reaction of this kind. The numbers in the extravasated blood varied, being small in some of the largest and most recent-looking extravasations, and in the blood which was within the vessels there were very few, although in some vessels several might be seen. The bacilli were also fairly numerous in the external coats of blood-vessels of the pia mater, sometimes forming a distinct pale blue ring around them. The blood-vessels of the pia mater were widely dilated and the walls presented hyaline changes and shedding of the endothelium; those of the veins and smaller vessels were in many cases necrotic and actually broken down. The brain substance was comparatively little affected; there were some œdema and disintegration of the superficial tissues where the blood had passed between it and the membranes; the chromatic granules were as well preserved as they are ordinarily found 30 hours after death; there was almost no extension of the hæmorrhage along the fine nutrient vessels of the cortex and the bacterial invasion of these vessels and their lymph spaces was practically coextensive with the hæmorrhage While no hæmorrhage in the substance of the brain was recognised with the naked eye the sections revealed a number of minute hæmorrhages deep in the cortex. The extreme dilatation of the medium-size vessels appeared to be the first stage of this, the wall finally disintegrating and the blood escaping to the surrounding lymph space or invading the soft brain substance. Anthrax bacilli were found only in two or three of the dilated vessels or the most recent hæmorrhages, although a large number were searched for them, but they appeared in considerable numbers in several of the hæmorrhages which were of somewhat larger size.

The organisms discovered in the films—viz., diplococci, bacilli like bacillus coli communis and oval bacilli with polar staining, long thin bacilli with terminal spores and a few [illegible]ts, were recognised in the sections, but by far the most numerous organism was the anthrax bacillus. A number of fragments of columnar epithelium were also found in the extravasated blood—a condition which is discussed below. The condition in the cerebellar was similar to that in the cerebral meninges but less advanced; here also it was most marked in the sulci.

The condition thus is clearly a hæmorrhagic meningitis in which, however, the inflammatory reaction in the ordinary sense is but little developed, probably on account of the extreme violence of the irritant.

The case then presents the appearance of an extremely violent attack of internal anthrax. Such cases, so rapidly fatal, are described by Bell[2] as not infrequent in pulmonary anthrax (wool-sorters' disease). The patients apparently receive a large dose of virulent anthrax bacilli or spores which constitute an invading force so overwhelming that they collapse almost without a sign of resistance. The actual illness may last a shorter time even than in the present case, and the total period from the contact with the infected material which is blamed may be less than 48 hours. In districts where the trades are pursued which are known to expose the workers to anthrax infection, such cases will probably not escape recognition. Where, as in the present case, there was nothing to connect the condition with anthrax, it is very different, and the *importance of post-mortem* examination can hardly be overstated As it was, the diagnosis, even at the examination, presented difficulties which might well occur again and deserve careful consideration. The illness was an acute one with implication of the nervous system as its only prominent feature, this being explained by the presence of a lesion of the meninges of recent origin. Elsewhere—viz., in the intestine—was found a lesion obviously of older date with corresponding changes in the mesenteric glands, and no other lesion of equal age was found on any other mucous surface and there was no external wound or œdema. In other respects the appearances were those of septicæmia. In the circumstances it is impossible to imagine the intestinal lesion the result of a general infection and we are forced to the conclusion that it was the site of entry of the infection.

It is unfortunate that the question of infection through the respiratory tract cannot be settled by microscopic examination. The œdema and hæmorrhagic infiltration of the mediastinal tissues and the pleuritic effusion are among the characteristic post-mortem appearances of the pulmonary form of anthrax as described by Greenfield,[3] but both of these might be phenomena of the general toxæmia which is shown in the condition of the spleen and kidneys and blood-vessels. On the other hand, the scarcity of anthrax bacilli in the mediastinal tissues and glands is in striking contrast to their abundance in the mesenteric glands, and the absence of characteristic naked-eye lesions of the lungs and bronchi was confirmed by several observers.

Infection through the intestine is the rarest form of anthrax in man although the commonest in cattle and horses Intestinal lesions associated with malignant pustule or carbuncle appear to have been recorded first by Fournier[4] about 1750. The connexion of the human malignant carbuncle and cases of malignant fever without external lesion with the charbon or anthrax of animals appears to have been recognised towards the end of the eighteenth century by Chabert[5] (1780). In the early part of the following century, intestinal lesions similar to those described by Fournier were noted apart from external pustules by Costa and Bertin.[6] Under the name mycosis intestinalis cases of general infection with intestinal lesions were recorded in Germany by Wahl[7] (1861), von Recklinghausen[8] (1864) and Buhl[9] (1868), who noted the resemblance of the lesion to the intestinal anthrax of cattle, and Waldeyer[10] (1871). Blavot,[11] in his account of an epidemic of anthrax in Strasburg in 1863, observed intestinal lesions, and in 1871 Münsch,[12] in investigating anthrax among hairworkers in Moscow, appears to have had to do with the three types—malignant pustule, pulmonary anthrax, and mycosis intestinalis—and to have recognised that they were all manifestations of one disease—anthrax. More recently, a number of papers on the subject accounting for about a dozen cases have been published in Germany. Many of these cases, however, were pulmonary anthrax with secondary intestinal infection.

Up to 1901, according to Bell, primary intestinal anthrax without external lesion had not been observed in this country, and although he states, without giving details, that it is not uncommon in countries where anthrax is of frequent occurrence, it is evidently a decided rarity. Cases of gastric or intestinal anthrax, either accompanying a malignant pustule (cases of Mahomed,[13] Newton Pitt,[14] Lucas,[15] and Bell) or associated with extensive lesions in the lungs (Poland), or of the œdematous and erysipelatous type of anthrax (Bell[16]) have been described, but for the most part the duration of the illness was much longer than in the present case and the gastric and intestinal lesions were held to be secondary. Poland[17] regarded his case as of the inhalation type but the intestinal lesions were large, and but for the fact that there was little alteration in the mesentery the case would well bear interpretation as primary intestinal anthrax.

The case reported by Scott[18] in 1901 is probably an example of primary infection of the stomach by hair but with an accompanying skin infection. The subject was employed in an upholsterer's workshop as a cleaner and the infection was traced to hair which was in use for stuffing chairs. Other cases occurred among hairworkers about the same time in Glasgow. The woman first noticed a pimple on her cheek which after some days developed into a typical malignant pustule. On the third day she had a rigor, on the eighth day she developed epigastric pain, and died on the tenth day of illness. "Malignant pustules of large size were found in the stomach while numerous smaller ones were found in the intestines. It is interesting to note in connexion with these pustules in the stomach and intestines that her brother voluntarily stated that the patient was in the habit of chewing hair." The forewoman at her place of work had noticed portions of the hair between her lips. In more recent literature I have found after fairly extensive search only one case in this country and a case recorded by Risel,[19] which will be referred to further for other reasons, and in both of these the intestinal lesion appears to have been secondary.

The flesh of animals which have died from the disease has frequently been eaten by man without ill-effects. Infection of cats, dogs, and pigs by other portions of the same meat has been recorded[20]; the different result in this instance may have been due to the meat in the case of man having been cooked, whereas in the case of the animals it was raw. Experimentally it has been shown, however, that carnivorous animals are much less readily infected by feeding than graminivorous animals. Man appears in this respect to resemble the former class, even secondary infection of the stomach and intestines being so rare that a relative immunity to this form of infection appears probable.

The diffuse meningeal hæmorrhage, which was responsible for the most striking clinical features of the present case as well as for the recognition of its nature, is in many respects of great interest. Hæmorrhage, more or less diffused throughout the pia-arachnoid, is not a very rare condition. It is the commonest form of cerebral hæmorrhage in infants, occurring at birth as a traumatic condition, while the cause of cases occurring later appears to be obscure. It is associated with convulsions, whooping-cough, and sinus thrombosis in wasting disease. It is said to have been seen in infantile tetanus. In adults it is met in association with injury and apoplexy and septic conditions. In apoplexy the blood tends, as a rule, to pass inwards into the substance of the brain rather than to diffuse itself through the pia-arachnoid, but in cases of hæmorrhage bursting into the lateral ventricles and arachnoid cisterns of the base of the brain a very general diffuse hæmorrhagic condition of the membranes has been observed, but the accumulation of clots about the base of the brain and in the ventricles produces a condition which could hardly be confused with the present. The closest resemblance to this condition which I have seen was observed in a case of multiple small lacerations of the cerebral hemispheres due to a fall without fracture of the skull, but the diagnosis presented no difficulty.

Pia-arachnoid hæmorrhage due to septic disease, according to Pye-Smith,[21] is not common; it occurs in blood poisoning, pneumonia, anæmia, and purpura. Coats[22] mentions in addition anthrax and ulcerative endocarditis. Scurvy is also mentioned. "Blood poisoning" and pneumonia are the commonest names under which unrecognised cases of anthrax in the beginning and course of epidemics are registered and purpura is a somewhat vague septic condition which might cover anthrax.

Although the records of hæmorrhagic meningitis are not numerous, it appears to be no great rarity in comparison with the total number of cases of human anthrax which prove fatal. Bell states that about 22 per cent. of the subjects of anthrax in the epidemics in Bradford and the neighbouring wool-manufacturing districts showed rambling of the mind and delirium, and of these five became comatose and three had convulsions (eight out of 87) and in most of these he believed that meningeal hæmorrhage had occurred. It was observed post mortem in three cases which are detailed by Greenfield[23] in his report on the Bradford epidemic. Risel has collected from German and English literature over 24 cases in which the condition was found. It is therefore perhaps not too much to say that in all cases of acute disease, especially if associated with septic phenomena such as enlargement of the spleen and mediastinal œdema, diffuse hæmorrhage into the meninges ought to awaken suspicion of anthrax.[24]

As regards the route by which the organisms reached the meninges there are three alternatives, of which two are allied. It appears to be taken for granted that, as a rule, they are conveyed by the blood stream. In Risel's collection there would come under this category all the inhalation cases, 12 in number, three of obscure internal origin, and five or six external, but there are four cases in which the pustule was situated on the face or neck, and in one of these (Ziemke's) the meningeal infection was regarded as having occurred through the lymphatics. There was great œdema of the neck with widespread infection of the lymphatics, which was held to have obstructed the lymphatics draining the cranial cavity and enabled the bacilli to travel back along them to the subarachnoid lymph spaces and their branches. In these cases no bacilli could be found in the blood. In the other cases the bacilli were found within the vessels, but as a rule were few in number in comparison with the immense numbers in the extravasated blood. In one or two the bacilli swarmed in the blood-vessels as in those of animals inoculated experimentally.

In the case recorded by Risel (Case 2 of his paper) the lungs were free from infection, there was a small intestinal pustule with limited infection of the mesenteric glands, and the most striking lesions were situated in the nose and pia mater. The nasal mucous membrane was swollen, infiltrated with blood, and flecked with bloody mucus. Anthrax bacilli were found in abundance in it at several points and there was a hæmorrhagic and leucocytic exudation containing bacilli in the perineural lymphatic channels of the olfactory nerves which was followed through the cribriform plate to the dura mater overlying it. There was an enormous pia-arachnoid hæmorrhage, the layer of blood beneath the arachnoid being one centimetre thick over certain parts of the cerebral hemispheres. There was much blood also about the base of the brain. The bacilli were present in large numbers in the extravasation and in the meshes of the pia-arachnoid, and especially in the lymph channels surrounding the blood-vessels of the meninges and the small nutrient vessels of the cerebrum, but they could not be found within the blood-vessels of the meninges. There were a few in the spleen and liver but none in the lungs or kidneys. Risel therefore appears to be justified in concluding that they had reached the soft

[24] I have to express my indebtedness to Dr. K. Landsteiner of Vienna, who had informed me that he had seen more than one post-mortem examination in which the discovery of diffuse pia arachnoid hæmorrhage gave the first wa[illegible] the pathologist had to deal with a case of anthrax.

could be made out above it. The fundus was hard and firmly contracted. On vaginal examination the face was reached high up in front; it was moveable above the brim and not attempting to engage. The right foot, also moveable, was lying just below the level of the face. The hand could be passed into the lower segment of the uterus all round the head and leg but above the head the position of the retraction ring was very marked. Under deep anæsthesia the foot could be brought down to the vulva but this traction did not alter the relation of the fœtus to the uterine wall. The whole uterus descended with the fœtus and when traction ceased the leg again receded to its former level. The measurements of the pelvis were taken and showed clearly that it was contracted; at the same time it was quite obvious that the difficulty in delivery was not now due to the contracted pelvis but to the retraction ring and the grip of the fundus upon the trunk of the fœtus. The head could not rise and the trunk could not descend when traction was made on the leg or the head. The head was perforated through the eye and after traction had been made with the cephalotribe without success the neck was severed with long scissors and the head was removed. Gentle traction on the leg at once delivered the fœtus. The clinical measurements of the pelvis were: *external conjugate*, 7½ inches; interspinous, 9½ inches; intercristal, 11¼ inches; diagonal conjugate, 4¼ inches; estimated conjugate, 3½ inches (high promontory). The patient made a good recovery after a long convalescence but the vagina became much contracted by bands of cicatricial tissue. The posterior wall of the upper half of the urethra sloughed and there was still incontinence of urine. The patient was a tall strong woman who showed no other signs of rickets and had no other deformity. The fœtus was not of excessive size and weighed seven pounds after perforation and measured 20 inches. Since writing this the patient has become pregnant.

CASE 2.—The patient was a married primipara at full term of pregnancy. Labour began about 11 P.M. on Dec. 27th. The attending medical man examined and found the os undilated but made out that the head was presenting. He also noted that the abdomen was very pendulous. A tight binder was applied and the patient was advised to lie on her back as much as possible. About 6 A.M. on the 28th the membranes ruptured and strong pains came on. The medical attendant found that the head, arms, and legs were presenting above the brim of the pelvis. The os uteri admitted three fingers. An anæsthetic was given and traction was applied to the legs with pressure put on the breech from above. After a prolonged unsuccessful attempt at delivery in this way the patient was sent to Guy's Hospital about 12 noon. On admission the patient was painfully conscious but free from pain. The pulse-rate was 160 per minute. There were great discolouration round the vulva and laceration of the perineum and vagina below. On abdominal examination much the same condition as in Case 1 was found. The fundus was hard and contracted tonically. The retraction ring could be made out placed obliquely and about four inches above the pubes. The uterus was not tender and all attempts at bearing down were absent. The fœtal head was felt plainly lying in front just above the pubes. It formed a hard round mobile swelling and could be pushed laterally for two inches or more in either direction. It seemed to be covered with a very thin dilated but lax lower segment of the uterus. On vaginal examination under an anæsthetic the head could be reached high up above the pubes in front, the right arm was hanging down beside it but the shoulders were held up above the retraction ring. The right leg was also hanging down behind and to the right of the head and arm. The head was perforated and crushed but traction with the cephalotribe failed to move the fœtus. Traction was then applied on the leg and after considerable difficulty the perforated head rose above the retraction ring and the fœtus was easily delivered. The patient died about half an hour later.

At the necropsy the uterus and vagina were dilated into one cylindrical canal and there was no rupture or tear in the genital tract except at the perineum. The post-mortem examination was made 24 hours after death and no sign of the retraction ring was found, nor was this very marked on examination after delivery. There was an oblique tear of about two inches in the left broad ligament behind and some of the veins at the base of the ligament had ruptured, giving rise to the half pint of free blood found in the peritoneal cavity. The rupture was situated low down and did not reach up to the uterus. There were considerable laceration and bruising about the vaginal outlet and the perineum was also torn. The mother was of good height (5 feet 6 inches) and showed no other deformity. The pelvis was removed from the body.

Description of the bony pelvis.—On inspection the pelvis showed a delicate formation and the generally contracted type without change of shape other than a slight obliquity towards the right. The outside measurements were: interspinous diameter, 8½ inches; intercristal diameter, 9½ inches; external conjugate, 6½ inches; *posterior interspinous*, 3½ inches; true conjugate, 4 inches; right oblique, 4½ inches; left oblique, 4¾ inches; maximum plane of expansion, 5 inches; minimum plane of expansion, 4½ inches; from the lower part of the pubes to the tip of the lower end of the sacrum, 5 inches; and interischial tuberosities, 4¼ inches. It will be noted that the left oblique diameter is a quarter of an inch longer than the right, due to slight flattening of the left iliac bone in front, so that the symphysis of the os pubis is pushed for a quarter of an inch to the right of the middle line. To be strictly correct, therefore, this is a generally contracted pelvis with a slight oblique tendency towards the right. Both hip-joints and spine were normal, so that it is difficult to explain how this slight oblique twist arose. The alæ of the sacrum were equal on both sides. It is thus obvious that the pelvic brim was quite able to accommodate the fœtal skull and there was ample room in the cavity to allow of its passage. The measurements in the first case were estimated by clinical means; in the second they are taken from the actual specimen removed from the body.

The details in the early stages of labour in both cases are not very trustworthy. The uterine contractions appear not to have been very marked and there seems to have been no violent or excessive action leading up to the tonic contraction. I think therefore that one must look upon the condition of the uterus as premature contraction and retraction. At the time of admission into hospital the two cases illustrated a similar state, both as to the fœtal position and the uterine action, with the exception that the head was extended in the first case and flexed in the second. The uterus may be described as consisting of two parts, an upper contracted *fundal portion*, containing the arched back of the fœtus, and the lower lax thin part, containing the moveable head and leg, and in Case 2 the arm in addition. Between the two compartments was the rigid retraction ring gripping the neck and thigh of the fœtus. The fundus was in tonic contraction and there was a complete absence of any driving down force; in fact, the uterus may be said to have prevented its own action, for the fœtus was held high above the brim, suspended by its back. Apart from the danger of rupture of the uterus traction on the leg failed because the head could not rise from below the retraction ring and traction on the head was equally useless because the shoulders could not descend from above the retraction ring. Although the pelvis in each case was moderately contracted it was playing no part in the prevention of delivery at the time of admission.

On making strong traction with the cephalotribe, applied to the fœtal head after perforation, it was extremely difficult to make the head reach the brim, and the traction had merely the effect of pulling both uterus and fœtus down together. The result was that when released the uterus again sprang back to its original position, dragging the fœtus with it. It is not easy to determine how this unusual condition came about, for the details of the early stages of labour are not full enough. Although the pelvis in both cases seemed large enough to allow the passage of the normal fœtal head, the contraction may have been sufficient to prevent the head primarily from settling into the brim. A face presentation resulted in the first case, but in the second flexion was undisturbed. The medical attendant attempted version in Case 1, and spontaneous version may have been in progress in Case 2. The uterus then went quickly into tonic contraction and, as it were, caught the fœtus while in the act of turning, and as contraction and retraction became more marked the presenting parts were actually lifted high up above the brim. In the second case the pendulosity of the abdomen was noted before labour had started; this suggests that the fœtal head had not settled into the brim at the commencement of labour. In neither case was there any evidence of moulding.

Treatment.—The condition is easily recognised from obstructed labour due to contracted pelvis. In the first place, the head is so moveable and high that it can only be reached made to bring about, if desirable, a moderate state of distension of the entire colon. *Simple injections* for retention in the bowel do not require the rectal tube which should be removed after the preliminary irrigation. They are conveniently performed with the help of a large surgical syringe.

2. *Injection and irrigation of the lower ileum.*—As a ready access to the small intestine was part of the object of the operation, in case it should have been diseased, and with a thought also for the requirements of typhoid fever cases, I directed most of the injections which I myself performed into the small intestine, having previously worked out the method in the dead body with Sir William Bennett. The *modus operandi* is simple and has been found quite easy by my house physicians as well as by myself. The catheter is bent (not too sharply) to about 110° at a point two and a half inches from its tip. It is to be introduced, not sagittally as when it is intended for use in the cæcum, but inwards and downwards as well as backwards in the direction of the nearest spot on the brim of the pelvis. The assurance that the catheter has entered the small intestine is given by the greater length introduced (maximum in this case nine inches), by the subjective sensations of the patient experienced in the hypogastrium even so far as the middle line, by the direct palpation through the abdominal wall sometimes obtained by the operator, and by the skiagram of the stilette *in situ*.[5]

3. *Systematic lavage of the lower ileum*, such as might be suitable for ulcerative typhoid fever, is best performed with two tubes instead of the single catheter. With the valuable assistance of Mr. Aylen I have satisfied myself in this case that a therapeutic lavage of the last portion (probably a foot or two) of the ileum could be readily achieved after a preliminary cleansing irrigation. For this special purpose I have introduced side by side a No. 2 gum catheter and a No. 6 gum catheter; but I should prefer the indiarubber instruments if made thinner in the wall. The small catheter is passed through the valve first, in the manner which I have described, to the distance desired, and the larger one is then introduced into the cæcum, where it acts as a draw-off for the fluid injected higher up. This arrangement might enable antiseptics to be used locally which it might not be desirable to expose to absorption by the mucous membrane of the entire colon. The quantity injected being noted evidence would be obtained that it had been duly recovered from the cæcum either by simple syphonage or if necessary by aspiration with the syringe. For this lavage the patient should assume a three-quarters right lateral decubitus to promote the descent of the injected fluid into the cæcum.

Although the experience which I have detailed has been gained in a single case it will probably apply in general outline to the majority of cases. The anatomical relation of the ileo-cæcal valve to the brim of the pelvis is not liable to much variation and that which exists between the valve and the entrance to the appendix is also fairly constant; it is in the direction taken by the tail of the latter that the chief individual differences are found and these would be eliminated by dividing the appendix high up. A short stump would also afford the advantage of a broader way into the bowel, although it might fail perhaps to provide for a faithful sphincter-like action.

Remarks on Appendicostomy and the Treatment of Typhoid Fever.

The answer to the question proposed by Mr. Keetley in THE LANCET of April 14th, "Ought not typhoid fever patients to be operated on before fatal perforation and bleeding occur?" must ultimately depend upon the results which may be achieved by early surgical interference when it comes to be tried. It is clearly too late to begin any local treatment of the bowel when the patient is *in extremis*. These resuscitation operations are a purely surgical concern and have nothing in common with the local therapeutic method for which surgical assistance may be desired by the physician. I may be allowed to state that the anxiety with which I have been credited by Sir William Bennett[6] and by Mr. Keetley[7] to utilise appendicostomy for the benefit of typhoid patients is in reality little more than a return to views which I had held for years as to the necessity for a local treatment of the ulceration presumably by a surgical route, until the favourable results yielded by the "empty bowel treatment," which I described in my last published clinical lecture on the Principles of Treatment of Typhoid Fever,[8] led me to hope that surgical help might be dispensed with. This apparent change of front is only as to the means. It is not due to any less regard for the "empty bowel treatment" but to a more personal acquaintance with the special facilities for local treatment combined in appendicostomy with a minimum of operative risk and of after trouble. Indeed, my obligation to Sir William Bennett for having for years discouraged my appeals for modes of interference offering doubtful surgical prospects is not less than that I owe him for having finally provided me with this more hopeful method; and once more the possibilities connected with surgical access to the bowel must command my careful consideration in spite of my recent disclaimer.

Mr. Keetley in the concluding paragraph of his important and suggestive paper alludes to some possibly superior advantages of enterostomy. Without presuming to discuss the surgical merits of the two operations, and although this is a purely academical stage in their discussion, I may perhaps record my preference for the less severe one which entails little interference with the intestinal economy, and in that sense affords much better scope for local medical treatment. For I cordially agree with Mr. Keetley's sentiment that "the operative treatment of typhoid fever ought not to mean taking the disease out of the physician's domain and transferring it to the surgeon's. It is a means of facilitating treatment by the physician."

I have briefly sketched the mechanical technique adapted for the "appendicotherapy" which may soon be made available for the treatment of the "typhoid segment" both when ulcerated and, perhaps better still, prophylactically prior to ulceration. Meanwhile, my therapeutic endeavour is not, either in this or in any other affection, to extend but rather to contract the surgical frontier. I still consider that the medical resources for the cure or the curtailment of the typhoid attack are by no means exhausted. But if the knife should prove to be an indispensable accessory to that achievement I should not decline its service. I also believe that Mr. Keetley's question as to the proper time for surgical interference would then be decided on grounds of public health; and that it would probably be decided in favour of a sterilisation of Eberth's bacillus *in situ intestinali* with a minimum of surgery and of the utmost reduction by that way of the spread of typhoid infection.

TWO UNUSUAL CASES OF DIFFICULT LABOUR.

BY H. T. HICKS, F.R.C.S. ENG.,
OBSTETRIC REGISTRAR AND TUTOR, GUY'S HOSPITAL; AND ASSISTANT SURGEON TO THE SAMARITAN FREE HOSPITAL.

CASE 1.—The patient, a married woman, aged 31 years, had had one full-term child, born dead after a prolonged labour which ended in a difficult forceps delivery; this was two years ago. She had now reached the full term of her second pregnancy. Labour pains began in the afternoon of March 27th. The os was only slightly dilated and the face was found presenting; the membranes ruptured about 9.30 P.M. As the face did not descend and the pelvis was contracted version was attempted by the patient's medical man about two hours after the membranes had ruptured. The face was lifted out of the brim without difficulty and the right foot was found close down beside the head. The head was said to be moveable. Traction on the leg failed to move the child and after a prolonged attempt, first at version and then at applying forceps to the head under an anæsthetic, the patient was taken to Guy's Hospital in the early hours of March 28th. On admission the pulse was 136 per minute but the general condition was fairly good. There were great swelling and bruising of the vulva and vagina. On abdominal examination the extended head could be felt easily just above the pubes in front; it was freely moveable and Bandl's ring hollow-ground scalpels, made by Messrs. Down Brothers to my design. The ordinary scalpel is quite unsuitable for skin division at any time unless extremely sharp. It is wedge shaped and, may I say, the worst treated of all instruments. Is it not thrown into the tray, on the bed, and generally neglected? If an ordinary scalpel is used in my new skin operation nine out of ten cases will prove a failure. There must be one clean cut without force. The ordinary scalpel used as it should be will seldom do this, but more often dissect up a quarter of an inch or more epithelial flap before penetrating the corium. My hollow ground scalpel must be used only for the purpose for which it is intended and substituted for the ordinary scapel as soon as the skin is divided. It must be treated with the greatest care and after stropping cleansed with ether and alcohol. Light spring tissue forceps, dissecting forceps, and sometimes lance-pointed needles and horse-hair sutures are required, as also are dressings, glass cover, collodion, silk, absorbent wool, bandages, and sometimes a back splint.

---

[5] Dr. Ewart showed us two skiagrams which we were unable to reproduce. The one showed the catheter lying in the ascending colon and the other showed it in the small intestine passing across from the right-hand side of the false pelvis, across the middle line till the point was lost about the brim of the true pelvis on the left-hand side.—ED. L.

[7] THE LANCET, April 14th, 1906, p. 1023.

[8] Brit. Med. Jour., Dec. 9th, 1905.

With regard to the operation itself, the skin should be reasonably stretched in all directions by assistants if this is not already the case by some underlying tumour. The angle at which the knife should be held can only be learnt by practice. The skin, as a rule, will give five or six millimetres or about a quarter of an inch flap, but in addition at least as much fat flap, except, of course, when the fat is excessive. Fat makes firm rapid union and is therefore of considerable importance. The knife should make one clean sweep down to the fascia, which in turn should be divided as far under the base of the upper flap as possible and on no account should the lower flap be dissected off this fascia. The upper flap is now inclosed in warm, dry, sterile lint and secured far back with tissue forceps. The lower flap being retracted on the fascia is treated in a similar manner and the operation for which the incision was made proceeds in the usual manner. If the operation is prolonged the warm, dry lint should be renewed.

The next step is the important one of adjustment. Upon the question of tension depends the necessity of a subcutaneous suture. I seldom use a suture but when I do it is as follows. I pass a lance-shaped slightly curved needle threaded with fine horsehair through the skin upon the slant at a little distance from one extremity of the wound; it then passes through the base of the upper and the apex of the lower flap continuously, its point of exit being through the skin on the slant at the other extremity of the wound. The suture is not tied and is removed at the end of 48 hours. Previously to inserting a suture, in all cases the following very important manipulation must be carried out. The object is to stretch the delicate apex of the upper flap, the least force will tear it off, therefore if forceps are used great care must be exercised. I find the best plan is gently to press this edge between the finger and thumb when it will be found gradually to yield; at the same time the lower flap must be stretched and placed in position with suitable forceps. The delicate edge is then carefully spread in its proper position, the accuracy of which is best tested with a good large magnifying glass. The subsequent object of dressing is to keep this edge, together with the rest of the flap, in accurate flat position, remembering that undue pressure may cause damage. Sometimes I secure the wound by placing across a few strips of China silk and collodion, at others by merely placing collodion on the curved or flat glass dressing. When the glass is pressed flat the exact position of the flap can be seen at a glance. I prefer glass to celluloid or mica because it is rigid, a matter of importance when applying pressure. In all probability excellent results will be obtained in a dozen other ways. I use glass because I am accustomed now to its manipulation, but I do not propose to go into any further details on this point at present. I published a paper[1] a little time ago giving some details, but I find that surgeons consider it is too much trouble, although they admit that the principle is correct.

With regard to pressure, it should be slight for the first few days, then gradually increased. Whichever rigid dressing is placed over the wound it should be covered by a large pad of wool. If no rigid dressing is thus used in all probability a contracted condition of the flap will result. Sooner than allow a wound to heal in bad position I would always break it down and begin again.

At the present time I am more concerned with the artistic effect produced when operating upon the more exposed parts of the body and particularly in those classes of society to which any undue blemish is of importance, especially in removing glands from the neck. The mechanical advantage of the operation in general I am well aware of. It is to be feared that only in these cases will the best results be obtained. We are all aware that wounds on the face heal rapidly but do they not invariably leave ugly scars? I prefer to deal with these cases by converting the accidental cut to one on the slant at or as near the time of accident as possible and I have no hesitation in breaking a recently healed wound for this purpose. In such cases where the operation has been performed by a consulting surgeon the general practitioner must be called in to play a most important part; not only should he personally be intrusted with the subsequent massage but also with the general supervision for a considerable period and this should in all cases be explained to the patient before operation. These results would seldom be obtained with the poor who would not be found to present themselves once the wound was healed. The difficulties of the operation are not many but they will be met with—a very thin skin over a tense cyst or abscess, and, on the contrary, a very lax condition of skin may tax the ingenuity of the beginner but not the experienced surgeon.

The very important question now to be considered is the one of massage. The massage of wounds and scars practically is not recognised and as a general rule may be said to be entirely neglected and yet is there any reason why it should not be carried out with as excellent result as in the case of bones, ligaments, muscles, &c.? The moment a wound has healed over, as a rule, it is left to its fate and only when the skin has formed firm adhesions and contractions is the damage realised. In any ordinary wound involving the whole thickness of the skin the scar may be prevented from forming adhesions; it may be stretched, softened, and in many other ways improved.

In the case of my incision upon the slant there is perhaps only a very small amount of scar tissue, but though unseen it is there. Proper massage and stretching if necessary will promote circulation, restore contour, and prevent subcutaneous adhesions. Few patients would submit themselves continuously to the consultant or general practitioner after all apparent reason had gone for so doing and therefore I am drawn to the conclusion that it is only by the coöperation of both that the best results will be obtained.

Wimpole-street, W.

BRONCHO-PNEUMONIA AND PYÆMIA.

By IVY McKENZIE, M.A., B.Sc., M.B., Ch.B. Glasg.,
CARNEGIE RESEARCH SCHOLAR, PATHOLOGICAL DEPARTMENT, WESTERN INFIRMARY, AND UNIVERSITY OF GLASGOW; LATE RESIDENT ASSISTANT PHYSICIAN, RUCHILL FEVER HOSPITAL, GLASGOW.

THE serious complications of measles are those which are associated with, or follow on, the initial catarrh of the respiratory passages, and of the complications the most serious is broncho-pneumonia. This condition may develop during the acme of the exanthem or it may not appear until the eruption has faded and the initial fever has passed off. The clinical symptoms and signs and the pathological appearances vary greatly: the disease may terminate fatally after two or three days or it may continue for three or four months and end in recovery. In some cases the symptoms of respiratory distress may be very alarming and the objective pulmonary signs very indefinite, while microscopic examination may be necessary to determine the nature of the lesion. In other cases respiratory difficulty may be absent and fever may never exceed 99° or 100° F. and for the most part be below 98·4°, while physical examination reveals the presence of extensive consolidation, and on post-mortem examination there may be found advanced lobular consolidation with acute vesicular emphysema. No less varied is the number of pathogenic organisms that have been found in the bronchial secretion and in the inflammatory exudate. These include Fraenkel's pneumococci, Friedlander's bacilli, staphylococci, streptococci, pseudo-diphtheritic bacilli, and bacilli coli. It is believed that the pneumococcus is present in the great majority of cases and it with difficulty with the cephalotribe or by long forceps; and, secondly, the uterus does not drive the presenting parts towards or into the brim, even though the latter could accommodate them. These facts are sufficient to make one suspect that the trouble lies at the retraction ring and not at the brim of the pelvis. It is of the utmost importance to recognise the condition because traction on the leg or on the head with forceps is not without danger. The treatment is clear. A blunt cephalic hook is passed round the neck of the fœtus in order to bring the head as low as possible. The neck is then cut through, either with scissors or with the sharp hook. The head is then crushed and delivered with the cephalotribe after perforation. Gentle traction on the leg will effect speedy delivery of the trunk. It was noted at the time that in both cases the uterus was not very hard and the patients suffered only slight pain. Ergot had not been given in either case.

---

[1] See THE LANCET, Nov. 18th, 1905, p. 1453.

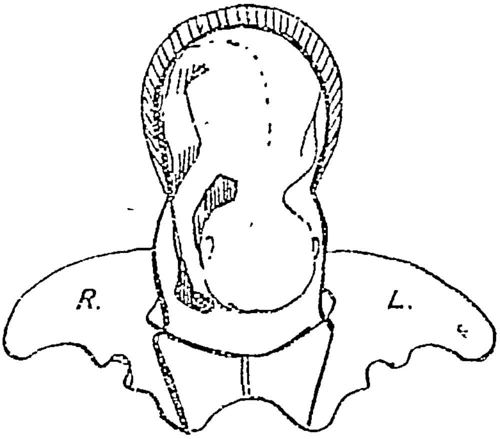

Diagram of the position of the fœtus in relation to the pelvic brim and uterus.

I have to thank Mr. J. H. Targett for kindly allowing me to describe these cases.

INVISIBLE SURGERY.

By J. L. A. AYMARD, M.R.C.S. Eng., L.R.C.P. Lond.

A METHOD of skin division without leaving a permanent visible scar would appear to most surgeons to be an impossibility and yet such is not the case. My new skin incision is by no means the result of a sudden inspiration but rather the outcome of a study of the important subject of scars in general. I notice with regret a tendency to resent details when issued by great surgeons and therefore fear that the present addition to what appears to be the simplest of operations may not be received without considerable irritation, and yet I will publish none which I do not consider essential to complete success.

My new method of skin division consists of the simple operation of dividing it upon the slant in contradistinction to the present method of dividing the same at right angles to the surface. My idea, though new by design, is by accident of very ancient origin. There are few of us who have not on our person some example, however small, of this cut through the skin upon the slant. Such a cut, if extensive, generally presents a somewhat lumpy appearance due to contraction and very often a smooth mark at the line of junction. It is a skilled application of the principle with scientific correction of the defects which give results entitling such a heading as appears to this article.

Before dealing further with this new incision it will be well to consider the one generally in use at the present time—namely, at right angles to the surface. The skin alone is in most places quite thin and were it not for the fat it would be most difficult to bring it in anything like contact. From experiments I have made I am inclined to think that, except in the immediate proximity of a suture, the tendency of the ordinary applied dressing is rather to cause separation than approximation. In any case, the result of a clean incision at right angles to the surface is always a white linear scar. A continuous suture gives no better result. The reason why a cut through the skin upon the slant and subjected to properly applied pressure heals so perfectly is not far to see. Contact is perfect and the greater the pressure within limits the better it is. I have proved beyond doubt granulation growth can be controlled by pressure and was therefore not in the least surprised to get such good results from this new incision. The ordinary process of healing proceeds as usual but granulation tissue with subsequent fibrous and scar tissue is reduced to a minimum. The scar is present but hidden away and, if I may quote, "What the eye does not see the heart does not grieve."

Fig 1

Section of New Skin Incision

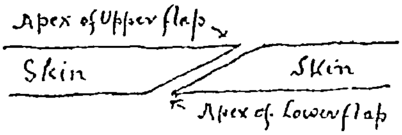

Fig 2

Shewing Contraction

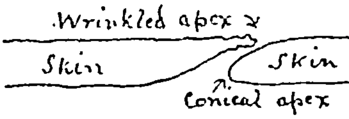

Fig. 1 gives a rough idea of the new incision. Fig. 2 gives also a diagrammatic appearance of the condition of the flaps directly after division.

It is of the greatest importance that we should grasp what takes place. The apex of the upper flap at once retracts and becomes wrinkled, curling inwards or outwards according to the region of the incision. The apex of the lower flap takes as a general rule a conical form. In the subsequent approximation these points should be borne in mind. It is not sufficient simply to adjust the wrinkled apex of the top flap.

Now as to the details of the operation, preparation of skin, anæsthetic, preparation of hands, light, instruments, dressings, and after treatment. All extravagant preparation of the skin is, I think, out of the question, the simple expedient of scrubbing with hot water and soap being quite sufficient, the skin being then protected with a warm dry sterile pad. The question of shaving the site of incision is a matter of some importance; shaving a hitherto unshaven part is apt to produce a vigorous growth of hair, and no lady in social position will thank you for this. I therefore consider it best to extract with forceps those hairs which are in the immediate neighbourhood of the incision, fixing others with collodion out of the way. In the case of a man, from whose cheek or chin I wish to remove a tumour, my plan is as follows. Allow two days' growth of hair, then extract as above in proximity to line of incision, then shave the whole surface. Any fear of hairs growing at once into the wound is avoided. Having done this I prefer the application of a warm dry pad, not a moist one, as the skin should not be macerated before operation. As to an anæsthetic, I generally prefer not to use a local one on account of the extra swelling. Hands are prepared in the usual manner, avoiding gloves; the latter will be found almost impossible in the delicate manipulation described later. An excellent light is, of course, essential when adjusting the upper flap, and a large magnifying glass is of great assistance.

Now as to instruments. The most important of all is, of course, the knife. My earliest efforts were made with an adapted hollow-ground r I now use most excellent hollow-ground scalpels, made by Messrs. Down Brothers to my design. The ordinary scalpel is quite unsuitable for skin division at any time unless extremely sharp. It is wedge-shaped and, may I say, the worst treated of all instruments. Is it not thrown into the tray, on the bed, and generally neglected? If an ordinary scalpel is used in my new skin operation nine out of ten cases will prove a failure. There must be one clean cut without force The ordinary scalpel used as it should be will seldom do this, but more often dissect up a quarter of an inch or more epithelial flap before penetrating the corium. My hollow ground scalpel must be used only for the purpose for which it is intended and substituted for the ordinary scapel as soon as the skin is divided. It must be treated with the greatest care and after stropping cleansed with ether and alcohol. Light spring tissue forceps, dissecting forceps, and sometimes lance-pointed needles and horse-hair sutures are required, as also are dressings, glass cover, collodion, silk, absorbent wool, bandages, and sometimes a back splint.

With regard to the operation itself, the skin should be reasonably stretched in all directions by assistants if this is not already the case by some underlying tumour. The angle at which the knife should be held can only be learnt by practice. The skin, as a rule, will give five or six millimetres or about a quarter of an inch flap, but in addition at least as much fat flap, except, of course, when the fat is excessive. Fat makes firm rapid union and is therefore of considerable importance. The knife should make one clean sweep down to the fascia, which in turn should be divided as far under the base of the upper flap as possible and on no account should the lower flap be dissected off this fascia. The upper flap is now inclosed in warm, dry, sterile lint and secured far back with tissue forceps. The lower flap being retracted on the fascia is treated in a similar manner and the operation for which the incision was made proceeds in the usual manner. If the operation is prolonged the warm, dry lint should be renewed.

The next step is the important one of adjustment. Upon the question of tension depends the necessity of a subcutaneous suture. I seldom use a suture but when I do it is as follows. I pass a lance-shaped slightly curved needle threaded with fine horsehair through the skin upon the slant at a little distance from one extremity of the wound; it then passes through the base of the upper and the apex of the lower flap continuously, its point of exit being through the skin on the slant at the other extremity of the wound. The suture is not tied and is removed at the end of 48 hours. Previously to inserting a suture, in all cases the following very important manipulation must be carried out. The object is to stretch the delicate apex of the upper flap, the least force will tear it off, therefore if forceps are used great care must be exercised. I find the best plan is gently to press this edge between the finger and thumb when it will be found gradually to yield; at the same time the lower flap must be stretched and placed in position with suitable forceps. The delicate edge is then carefully spread in its proper position, the accuracy of which is best tested with a good large magnifying glass. The subsequent object of dressing is to keep this edge, together with the rest of the flap, in accurate flat position, remembering that undue pressure may cause damage. Sometimes I secure the wound by placing across a few strips of China silk and collodion, at others by merely placing collodion on the curved or flat glass dressing. When the glass is pressed flat the exact position of the flap can be seen at a glance. I prefer glass to celluloid or mica because it is rigid, a matter of importance when applying pressure. In all probability excellent results will be obtained in a dozen other ways. I use glass because I am accustomed now to its manipulation, but I do not propose to go into any further details on this point at present. I published a paper[1] a little time ago giving some details, but I find that surgeons consider it is too much trouble, although they admit that the principle is correct.

With regard to pressure, it should be slight for the first few days, then gradually increased. Whichever rigid dressing is placed over the wound it should be covered by a large pad of wool. If no rigid dressing is thus used in all probability a contracted condition of the flap will result. Sooner than allow a wound to heal in bad position I would always break it down and begin again.

At the present time I am more concerned with the artistic effect produced when operating upon the more exposed parts of the body and particularly in those classes of society to which any undue blemish is of importance, especially in removing glands from the neck. The mechanical advantage of the operation in general I am well aware of. It is to be feared that only in these cases will the best results be obtained. We are all aware that wounds on the face heal rapidly but do they not invariably leave ugly scars! I prefer to deal with these cases by converting the accidental cut to one on the slant at or as near the time of accident as possible and I have no hesitation in breaking a recently healed wound for this purpose. In such cases where the operation has been performed by a consulting surgeon the general practitioner must be called in to play a most important part; not only should he personally be intrusted with the subsequent massage but also with the general supervision for a considerable period and this should in all cases be explained to the patient before operation. These results would seldom be obtained with the poor who would not be found to present themselves once the wound was healed. The difficulties of the operation are not many but they will be met with—a very thin skin over a tense cyst or abscess, and, on the contrary, a very lax condition of skin may tax the ingenuity of the beginner but not the experienced surgeon.

The very important question now to be considered is the one of massage. The massage of wounds and scars practically is not recognised and as a general rule may be said to be entirely neglected and yet is there any reason why it should not be carried out with as excellent result as in the case of bones, ligaments, muscles, &c.? The moment a wound has healed over, as a rule, it is left to its fate and only when the skin has formed firm adhesions and contractions is the damage realised. In any ordinary wound involving the whole thickness of the skin the scar may be prevented from forming adhesions; it may be stretched, softened, and in many other ways improved.

In the case of my incision upon the slant there is perhaps only a very small amount of scar tissue, but though unseen it is there. Proper massage and stretching if necessary will promote circulation, restore contour, and prevent subcutaneous adhesions. Few patients would submit themselves continuously to the consultant or general practitioner after all apparent reason had gone for so doing and therefore I am drawn to the conclusion that it is only by the coöperation of both that the best results will be obtained.

Wimpole-street, W.

BRONCHO-PNEUMONIA AND PYÆMIA.

BY IVY McKENZIE, M.A., B.Sc., M.B., CH.B.GLASG.,
CARNEGIE RESEARCH SCHOLAR, PATHOLOGICAL DEPARTMENT,
WESTERN INFIRMARY, AND UNIVERSITY OF GLASGOW; LATE
RESIDENT ASSISTANT PHYSICIAN, RUCHILL FEVER
HOSPITAL, GLASGOW.

THE serious complications of measles are those which are associated with, or follow on, the initial catarrh of the respiratory passages, and of the complications the most serious is broncho pneumonia. This condition may develop during the acme of the exanthem or it may not appear until the eruption has faded and the initial fever has passed off. The clinical symptoms and signs and the pathological appearances vary greatly: the disease may terminate fatally after two or three days or it may continue for three or four months and end in recovery. In some cases the symptoms of respiratory distress may be very alarming and the objective pulmonary signs very indefinite, while microscopic examination may be necessary to determine the nature of the lesion. In other cases respiratory difficulty may be absent and fever may never exceed 99° or 100° F. and for the most part be below 98 4°, while physical examination reveals the presence of extensive consolidation, and on post-mortem examination there may be found advanced lobular consolidation with acute vesicular emphysema. No less varied is the number of pathogenic organisms that have been found in the bronchial secretion and in the inflammatory exudate. These include Fraenkel's pneumococci, Friedländer's bacilli, staphylococci, streptococci, pseudo-diphtheritic bacilli, and bacilli coli. It is believed that the pneumococcus is present in the great majority of cases and it has been found by me in pure culture and associated with other organisms in 26 out of 34 cases examined. Not infrequently organisms may be found in the blood. In the examination of 12 cases, eight before death and four after death, in four of those examined before death organisms were found (two pneumococci, one staphylococci, and one streptococci), while in three out of the four examined after death organisms were found (one pneumococci, one staphylococci, and one bacilli coli). A case has recently been observed which constitutes a type altogether different from any of the many varieties usually seen and described. In this case, very acute in its course, the constitutional and nervous symptoms overshadowed the respiratory symptoms. The ultimate examination showed it to be a case of broncho-pneumonia giving rise to pyæmia and solely due to the staphylococcus aureus. It is, moreover, the only case in a series of 34 examined in which the staphylococcus aureus was present unassociated with any other organism. The case presents features of a singular character, interesting from both a clinical and pathological standpoint. It is the only case of its kind noted in the clinical observation of 1000 cases of measles and in the pathological examination of 130 cases of broncho-pneumonia.

---

[1] See THE LANCET, Nov. 18th, 1905, p 14[illegible]

A boy, aged one year and eight months, came under observation on Sept. 26th, 1905. He was quite well until the 23rd when he took a "cold in the head." The eyes and nose discharged, cough was frequent, and he was not disposed to take his food. These symptoms increased in severity and were subsequently accompanied by considerable restlessness, until on the morning of the 26th a rash was noticed on the face. On the evening of the same day he was admitted to a measles ward in hospital. With regard to his previous health the child was said to have been healthy till the onset of the present illness. As to his family history and social conditions, the father and mother were alive and well. The patient was one of a family of four, all of whom were in good health. There was no evidence of constitutional disease in the history. He lived with his parents and three elder brothers in a house consisting of a room and kitchen, which was said to be well lighted and ventilated. He had always had plenty of nourishing food.

On admission (on the 26th) he was restless and slightly delirious. He was well nourished and developed. There was a profuse morbilliform rash all over the body. The conjunctivæ were suffused, the face was swollen, and rhinitis was present. The tongue was coated with a brown fur and Koplik's spots were present on the buccal mucosa. The throat was congested but there was no ulceration. The chest on inspection was seen to move freely and equably; the respirations numbered 52 per minute but were not laboured. On percussion the note over the pulmonary area was resonant throughout and on auscultation the respiratory murmur was everywhere accompanied by a moist inspiratory râle and an occasional wheezing râle; there was no evidence of consolidation. Cough was infrequent but secretion was not ejected. The area of cardiac dulness was marked on the right by the left sternal border, on the left by a line a quarter of an inch inside the nipple line and above by the third rib. The apex impulse was in the fourth interspace and a quarter of an inch inside the nipple line; the heart sounds were distinct, of good tone, and free from murmur. The pulse was regular in force and rhythm, of fairly good quality, and numbered 148 per minute. The abdomen was flaccid and the liver could be felt projecting beneath the right costal margin but the spleen could not be detected. The pupils were equal and reacted normally. The temperature was 101·2° F. On the 29th the progress of the patient was not satisfactory. Although the measles rash had disappeared there was no abatement of the fever and contitutional symptoms. The suffusion had disappeared from the conjunctivæ but the eyes had a clear, bright, and glassy appearance which was unnatural. There was still a considerable amount of restlessness and during the previous night (the 28th) he slept very little. The restlessness, moreover, was accompanied by a muttering delirium and while there was general nervous activity there appeared to be no cognisance of, or voluntary response to, surrounding influences. At times there was rolling of the eyeballs; the pupils were equal, moderately dilated, and reacted normally; the fundi oculorum appeared to be normal. There was no direct evidence pointing to a meningeal affection. Examination of the bones revealed nothing to account for the restless and delirium. The temperature had not been high since admission; only on one occasion, when it registered 103·2°, had it risen above 102°. The colour was said to vary from time to time; at one time he was flushed and at another pale and blanched. The respirations, while they did not vary much in rhythm, were at times somewhat laboured. The chest moved freely and equably on respiration; the percussion note was still normal throughout; at the left base and extending up to the angle of the left scapula and into the left axillary region there was an area over which the inspiratory part of the respiratory murmur was accompanied by an articulate crepitant râle. At no part, however, could the breathing be said to have a tubular quality. Pleural friction was distinct in the left axillary region. The upper part of the left lung and the whole of the right lung were free from signs which would indicate serious complication. The condition of the heart had not changed. The pulse was regular but soft and easily compressed and numbered 148. The tongue was parched and coated with a brown fur. The throat was still slightly congested. The bowels moved regularly and the stools appeared to be normal. The patient took his nourishment willingly.

On Oct. 1st the child's condition had become progressively worse. Delirium was still present, the restlessness was extreme, and the keen glassy appearance of the eyes at once attracted attention. The temperature was not high, ranging a short distance on either side of 102°. The colour was pale with occasional flushings. The respirations varied from 50 to 60 per minute; the evidence of pulmonary complication was now unequivocal; all over the left base the percussion note was dull and resistant and the respiratory murmur was replaced by extremely tubular and superficial breath sounds. An exploratory puncture was negative. All over the rest of the chest there were occasional moist and wheezing râles accompanying the respiratory murmur, but at no other part was consolidation detected. The area of cardiac dulness had not changed. The first sound was weak and somewhat indefinite in tone but the second sound was distinct and emphatic. The pulse was regular in force and rhythm but easily compressible and numbered 140 per minute. The patient was having ten minims of a 10 per cent. solution of camphor every four hours. He took his nourishment of milk and water willingly; the stools were loose and very offensive and contained undigested material; he was rapidly losing flesh and a diet of raw meat juice and whey had been resorted to. On the 3rd any change that had taken place had been for the worse; there had been progressive emaciation and the patient was now very weak. The delirium was still present but the restlessness was modified; the eyes had still their bright, sharp appearance; the pupils were equal and reacted normally and the fundi oculorum were normal. The tongue was dry and coated. The patient did not take his nourishment willingly and there had been occasional vomiting. The stools were very offensive and loose. A specimen of the urine was acid in reaction, contained a trace of albumin, but no blood or tube casts. The physical signs in the chest pointed to a rapidly advancing process. The whole basal region of the left lung was quite dull to percussion and the breathing in this situation was exquisitely tubular. Exploratory puncture again gave negative evidence. On the right side of the chest a resonant note was found throughout, although there was a relative increase in the resistance to the percussing finger, as examination was carried from the axillary region to the vertebral column. At the angle of the right scapula the respiratory murmur was replaced by breathing of a tubular quality and crepitant râle was abundant; these signs of consolidation were present all over the posterior aspect of the right lung, but diminished in amount in proportion to the distance from the inferior angle of the scapula. In the right axillary region pleural friction was heard. The area of cardiac dulness extended on the right to the mid-sternal line and on the left to the nipple line and upwards to the third rib. The first sound was toneless and at times the second sound was indistinct. The pulse was regular in rhythm but irregular in force and was very feeble even at the acme of its strength. It numbered 180 per minute. The patient died at 2 A.M. on the morning of the 4th.

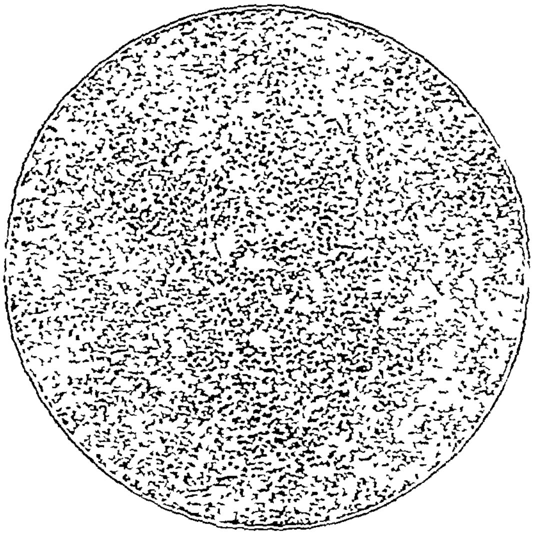
Summary of clinical history.—A child, aged one year and eight months, strong and well nourished and with a history of good health, was found suffering from an attack of measles associated with delirium. The rash appeared on the fourth day of illness and on that date, except for the delirium, there was nothing exceptional about the case. On the sixth and seventh days of illness the rash had almost gone, but the temperature had not settled and the child was very restless and delirious. Evidence of commencing pulmonary consolidation could be detected at the left base but the nervous symptoms were not such as one might expect at the beginning of an uncomplicated pneumonia with moderate temperature (102°). Examination of the nervous system and of the bones afforded no evidence of the presence of meningitis or osteomyelitis. On the ninth day of illness delirium was still present and consolidation at the left base was so advanced as to suggest the presence of fluid. The patient died on the eleventh day from the onset of the measles-symptoms and on the eighth day from the appearance of the rash and on the fifth day from the detection of the broncho-pneumonic signs. The most prominent features of the case were the persistent delirium with moderate temperature and the very rapid and advanced consolidation of the left pulmonary base.

Necropsy.—At the *post-mortem* examination the body was found to be well developed but poorly nourished, subcutaneous fat having almost entirely disappeared. The muscles were pale. There was slight congestion of the tonsils and pharynx but no evidence of ulceration. The mucous membrane of the larynx and trachea was greyish red, contained several ecchymosed patches, and was covered at parts with thin purulent secretion. There was no fluid in either pleural cavity. The left lung weighed eight and a quarter ounces; from its bronchus there exuded a quantity of thick creamy pus. The upper lobe with the exception of the atelectatic lingula was crepitant throughout, while the lower lobe was firm, œdematous, and non-crepitant. The upper lobe weighed one and three-quarter ounces, while the lower lobe weighed six and a half ounces and sank readily in water. The upper lobe had a pale greyish appearance except the lingula which was bluish-red. The lower lobe was dark red in appearance, presented numerous minute sub pleural hæmorrhages, and was covered in its posterior aspect with a thin fibrinous exude. On section the upper lobe, except for the lingula, was inflated throughout its extent. A small quantity of thin purulent secretion was present in the bronchioles. The lower lobe was quite hepatised and from the cut surface there exuded a bloody and serous exudate, while thick creamy pus could be expressed from the bronchial apertures. The right lung weighed four and a quarter ounces and floated in water. A thick muco-purulent secretion could be seen in the bronchus. On its posterior aspect there was a layer of fibrinous exudate and posteriorly the organ had a brownish-red appearance with areæ of lobular collapse, while anteriorly the lung was grey in appearance and crepitant throughout. On section, a narrow strip of consolidation bordered the posterior aspect of the lung, varying in thickness from one-eighth of an inch to half an inch, and thickest at the centre of the posterior aspect of the lower lobe. From the bronchi there could be expressed drops of creamy purulent material; the bronchial mucous membrane was deeply injected. The bronchial glands were large, pale, and soft. The pericardial sac contained about one and a half ounces of straw-coloured fluid. The heart was contracted; at the extreme left of the base was a small area, about half a square inch in extent, rough and coated with a fibrinous exudate. The left ventricle was empty, the left auricle contained some partly coagulated blood, and in the right chambers were large white moist fibrin clots. Close examination of the mural endocardium revealed the presence of small yellowish specks which were about one millimetre in diameter (Fig. 2). The valves and great vessels appeared to be normal. The cardiac muscle was pale and soft. The abdominal cavity was devoid of fluid. The liver weighed 16 ounces; it was brownish red in colour, with scattered pale areæ of about a quarter of a square inch in extent. Very minute yellowish specks from one millimetre to two millimetres in diameter were seen on the surface. The hepatic tissue was slightly congested and the gall-bladder was distended. The spleen weighed one and a quarter ounces. It was somewhat congested, of firm consistence, and the follicles were distinctly swollen. On the surface were seen minute yellowish specks, as in the liver and heart. The kidneys each weighed one and three quarter ounces. They were pale in appearance and the capsule came off easily. On the surface could be seen small yellow specks, rather larger than those in the liver and spleen, and section showed them to be minute abscesses. The cortex was yellowish-brown and the pyramids were pale. The mesenteric glands were pale, swollen, and soft. The stomach contained some greenish fluid and the mucous membrane, which was pale, was covered in parts with bile-stained slimy mucus. The skull appeared to be normal. The sinuses of the dura mater and the veins of the pia mater were distended with blood. The convolutions appeared to be distinctly flattened. The brain substance was soft, pulpy, œdematous, and anæmic, only the larger vessels containing blood. The ventricles were moderately distended and contained each about two ounces of clear serous fluid.

Bacteriological examination.—1. Film examination. Examination of smears from the bronchial exudate, pneumonic exudate, and spleen pulp showed the presence of Gram-staining micrococci, apparently staphylococci. 2. Cultural examination. Tubes of bouillon inoculated from the pneumonic exudate, spleen pulp, pericardial fluid, and cerebro-spinal fluid, and grown at 37° C., showed at the end of 24 hours growths of staphylococci. Separation cultures were made from the bouillon on to agar slopes and Petri's capsules and these presented colonies of staphylococcus aureus only. 3. Inoculation. From a fresh sub-culture of the growth in bouillon intra-peritoneal inoculation of a mouse caused death in 18 hours from septicæmia due entirely to staphylococcus aureus, and subcutaneous inoculation resulted in abscess formation with recovery.

Histological examination.—Histological examination of the tissue of the left lower pulmonary lobe pointed to an advanced inflammatory condition, commencing in the bronchioles. The smaller bronchi and bronchioles were filled with purulent and mucous material, together with desquamated epithelium and a few blood cells; the peri-bronchial capillaries and arterioles were very much dilated. (Fig. 1.) Some of the alveoli in the neighbourhood of the bronchioles showed the presence of a fibrinous exudate. The lung parenchyma, which appeared to be affected throughout, presented two kinds of changes: 1. Areæ in which there was dense purulent infiltration of alveoli, more especially in the neighbourhood of bronchioles. In addition to the numerous pus cells there were degenerate epithelial cells, a very few blood cells, and granular débris; the capillaries and arterioles were distended. 2. Areæ in which the changes were not so advanced; here the alveoli were small, the epithelium was swollen, with indistinct nuclei; there were numerous desquamated epithelial cells and granular débris; a few polymorphs and free blood cells were also present; the capillaries and arterioles were distended; the changes in these areæ corresponded exactly to the description given by Aufrecht of what he terms "alveolar atelectasis." Gram-Weigert stained sections showed, in addition to the fibrinous exudation in the alveoli near the bronchi, isolated cocci in the purulent contents of the alveoli and bronchi, and also

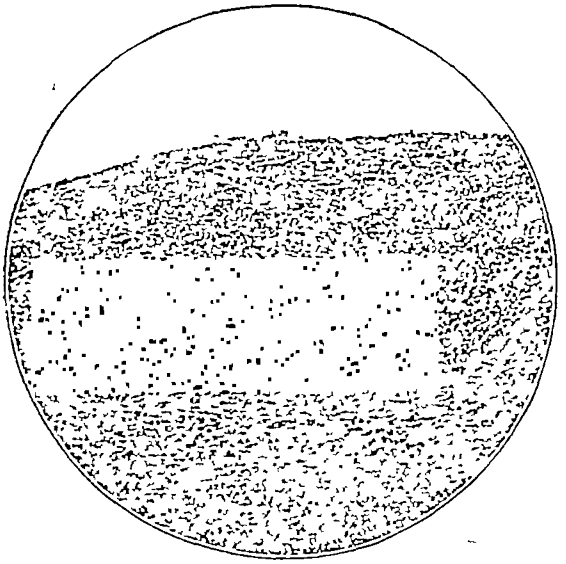
FIG. 1.



Bronchiole filled with purulent exudation. The surrounding pulmonary tissue is infiltrated and the peri-bronchial capillaries are dilated. × 100 Stain, hæmatoxylin and eosin.

groups of cocci in the arterioles (bronchial) and capillaries. Examination of the heart, liver, spleen, and kidneys showed, in addition to the cloudy swelling usually seen in acute febrile conditions, the presence of a large number of minute abscesses varying in size from one millimetre to two millimetres in diameter. Gram-Weigert stained sections showed cocci in these abscesses and, in addition, minute arterioles and capillaries plugged with staphylococci. The condition in the heart might be taken as representative of what is seen in the other organs. Fig. 2 shows a small abscess beneath the endocardium and Fig. 3 a capillary loop plugged with staphylococci.

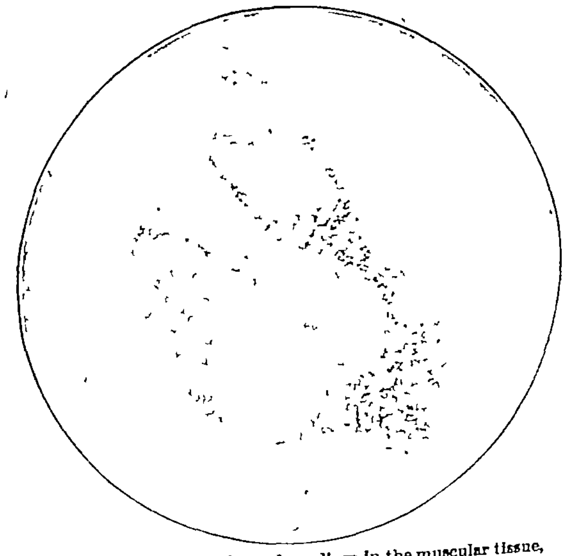
FIG. 2.



Small abscess beneath the endocardium, showing a limited purulent exudation with the remnants of a few muscle fibres. × 100. Stain, hæmatoxylin and eosin.

Conclusions.—The main interest of the case arises from the relation of the symptoms to the pathological findings. While in measles, especially in young children, a certain amount of nervous disturbance not infrequently accompanies a high temperature, with the decadence of the fever the nervous symptoms always disappear. A true meningitis has not been recorded as complicating the onset of measles. In broncho pneumonia, on the other hand, children often show signs of nervous disturbance; a commencing pneumonia is not infrequently associated with an appearance of nervous depression, the child being dull, languid, and apathetic, while in other cases there is a considerable restlessness. It is, however, in advanced and protracted cases that evidence of cerebral disturbance is most frequently seen; in such cases there is incessant restlessness, sometimes convulsions, and subsequent rigidity or paresis of muscles. These cases are usually fatal and on post-mortem examination no abnormality of the brain or meninges can be detected microscopically. In other cases, again, a pneumococcic meningitis with the usual signs and symptoms may complicate the broncho-pneumonia.

FIG. 3.



Capillary loop beneath the endocardium in the muscular tissue, plugged with staphylococci. × 1000. Stain, Gram.

The case under consideration presented evidence of nervous disturbance which, while it suggested meningitis, resembled more the extreme restlessness and delirium usually associated with acute osteomyelitis, acute phlegmonous cellulitis, or a very severe scarlet fever intoxication. The pathological examination, in view of the clinical symptoms, suggests the idea that there occurred in the lungs a severe inflammation the constitutional clinical manifestations of which resembled those of acute inflammation of bone or cellular tissue. The history of the case may be considered as (1) an inflammation due to the presence of a virulent form of staphylococcus aureus, beginning in the smaller bronchi and giving rise to the signs of a pulmonary consolidation; (2) the rapid progress and profuse infiltration and exudation giving rise to complete consolidation and atelectasis of the left lower lobe; and (3) the exalted virulence of the organism producing such a growth in the blood as to give rise to embolic infections of the various internal organs, leading to small abscess formations; and (4) the whole process resulting from infection by a highly virulent organism, the constitutional symptoms of intoxication overshadowed the effects of the local pulmonary lesion.

I am indebted to Dr. A. Johnston, physician superintendent of the Ruchill Fever Hospital, Glasgow, for permission to publish this case.

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

A CASE OF TUBERCULOSIS PULMONALIS WITH SOME SYMPTOMS OF MENINGITIS; RECOVERY.

By WILLIAM BERTRAM HILL, M.B., CH.B. VICT.,
RESIDENT MEDICAL OFFICER TO THE LEEDS SANATORIUM FOR CONSUMPTIVES.

THE patient was a man, aged 26 years, who was admitted into the Leeds Sanatorium for Consumptives on Oct. 3rd, 1905, suffering from pulmonary tuberculosis which involved the upper and middle lobes of the right lung. On admission he weighed 9 stones 11½ pounds and measured 5 feet 10¼ inches in height. His temperature at 4 P.M. was 99·2° F.; his pulse and respirations were respectively 78 and 20 per minute. His sputum measured about a quarter of an ounce daily; tubercle bacilli were present. There was marked dulness over the upper and middle lobes with bronchial breathing and whispering pectoriloquy; there were no râles. He was ordered to spend the whole day in the open air and his exercise was limited to one mile. He remained in this condition until Oct. 22nd, on which day his temperature varied from 100·2° to 101°; his pulse and respirations were respectively 80 and 18 per minute. His bowels were constipated. He complained of slight headache and vomited twice after food. On the 23rd his temperature varied from 99 2° to 102 8°; his pulse and respirations were respectively 80 and 18 per minute; his bowels were confined, his headache was more severe. On the 24th his temperature was still higher, reaching 105° at 4 P.M. The pain in the head was much increased; it was vertical in character, continuous, and at times was so acute that he cried out. He vomited after taking soda water and milk. His pulse was 80 per minute, full and bounding in character. At time she was slightly delirious. On the 25th it was noticed that there was an internal strabismus of the right eye and that the pupils were contracted, but reacted to light and accommodation. The patient himself complained that he did not seem to see rightly. Ophthalmoscopic examination, however, revealed nothing abnormal. His temperature varied from 104° to 105°. Constipation and vomiting were present. The patient remained in this state until Nov. 7th. The strabismus was now well marked and complete constipation and severe headache were present. Only milk in small quantities was administered and this was occasionally returned. Ice was kept to the head and enemata and calomel were given to overcome the constipation. The muscles of the legs and arms showed neither paralysis nor rigidity and there were no convulsions. No enlargement of the spleen was made out, neither was there any involvement of the sphincters. The temperature still remained between 103° and 105° and was controlled by tepid sponging. At times the patient was slightly comatose. Occasionally, especially towards morning, he broke out in profuse sweats. On Nov. 7th he became a little clearer mentally and his temperature was slightly lower, varying from 100° to 100·4°. The headache was not so severe but the squint was still well marked. On the 8th his temperature varied from 99·6° to 100°; his pulse and respirations were respectively 80 and 20 per minute. The squint was still present. His mental condition was much improved and he was able to take more nourishment. On the 9th the temperature varied from 99° to 100°; the pulse and respirations were respectively 80 and 20 per minute. The squint was not so marked and the bowels were opened naturally. From this date the patient improved rapidly each day, the squint gradually disappearing and the temperature becoming lower, until it reached normal on the 14th, by which time also the eye symptoms had quite disappeared. Examination of the chest showed that there had been no increase in the physical signs. He remained in the sanatorium until January, 1906, on which date he was discharged. He then weighed 9 stones 12 pounds, the temperature was normal, and there was no sputum; his chest signs were as on admission. He was last seen on March 6th. There was then no increase in the physical signs and no loss of weight. His temperature was normal and his eyes were perfectly normal.

I am indebted to Mr. Herbert de Carle Woodcock for permission to publish this case.

A SEVERE CASE OF MYOCLONUS MULTIPLEX.

BY CAMPBELL DYKES, M.B. LOND.,

CAPTAIN, I.M.S.

THE patient, who was a man, aged about 35 years—a Hindu and a Brahmin by caste—first came under observation in July, 1905. The muscular spasms of which he complained had then been noticed for five months. The left arm was first affected, then the neck, and later the right arm. When he was first seen the whole upper part of the body was in a state of constant jactitation, the arms were violently extended at the elbows, the spine was arched, the head was over-extended, and the shoulders were drawn back. Neither the patient nor any of his family had ever suffered from epilepsy or any other nervous disorder.

On the patient's admission to hospital the earliest stage of the disease was seen in the rectus and obliquus externus abdominis and the gluteus maximus and tensor vaginæ femoris of both sides. In these muscles momentary contractions of a limited portion of the muscle were seen to occur, occasionally single but more often in definite groups of four or five occurring together. The corresponding muscles of opposite sides were involved but did not contract synchronously. So far the patient was completely unconscious of this early stage of the disease. A much more advanced stage was illustrated in the upper limbs, neck, and back. At uncertain and variable intervals a muscle or group of muscles, such as the triceps, the trapezius, or one or more of the muscles attached to the vertebral border of the scapula, suffered a succession of contractions, following each other so rapidly that a more or less complete "tonus" was produced. The bulk of muscle affected here—in contradistinction to those first described—was so considerable that "locomotor" effects were produced: the forearm was forcibly extended on the arm and the head on the trunk, the trunk itself was arched backward, and the shoulders were drawn back. When the attack was at its height several or all of these effects were produced together or followed each other in rapid but irregular sequence. Each contraction appeared to last two or three minutes, then followed a short period of rest, then a fresh series of contractions, till apparently sheer exhaustion of the muscle brought temporary relief. The flexor muscles of the arms and the deltoids as also all the muscles of the forearm remained unaffected. The pectorals were for a long time unaffected but have recently shown the partial contractions described in the case of the abdominal muscles.

The muscles of opposite sides of the neck and trunk usually act coördinately producing extension directly backwards, but occasionally one sterno-mastoid contracts alone and lateral flexion of the lumbar spine has been recently noticed to occur. Voluntary movements of the upper part of the trunk and upper limbs are naturally much interfered with but can be fairly accurately executed if they require but momentary effort. There is no true ataxy. The gait is affected only indirectly. It remains but to notice that while the extrinsic muscles of the eyeballs have escaped, the orbicularis palpebrarum shares in the spasms which during their continuance can only be momentarily checked by voluntary effort so as to allow of a single glance being directed at an object. Extraordinary facial contortions are produced by irregular contractions of the lip and face muscles.

The patient himself believes that the movements are less violent when he is lying down than when he is sitting or standing, but I cannot satisfy myself that this is so. The movements cease entirely during sleep and his general health is unaffected except by the painful fatigue which results from the muscular contractions. The knee-jerks are exaggerated. There is no ankle clonus or any affection of sensation.

Of late the disease has begun to affect some fresh muscles, the hamstrings, pectorals, temporals, and masseters, and during the eight months that he has been under observation the abdominal muscles, of which at first only small segments suffered, have become more severely affected. Great relief has been experienced from the use of preparations of belladonna, whether administered internally in the form of the extract or hypodermically as a solution of atropine, and from the application of the constant current to the spine. The amelioration, however, is very temporary, lasting only for two or three hours or less. No benefit has resulted from the use of arsenic or bromide, though pushed to the limit of toleration.

Shortly after the onset of the disease the patient began to take opium but although he has taken as much as 24 grains a day no good effect can be attributed to it. In spite of the temporary mitigation of symptoms by treatment, the disease shows a distinct tendency to increase both as to violence of movement and as to the groups of muscles involved. Appetite and sleep remain unimpaired as yet but the patient finds his condition so miserable, partly from his inability to follow any of his ordinary occupations or even to feed himself without great difficulty and partly from his having become an object of ridicule or aversion to his neighbours, that he has already once attempted suicide by throwing himself into the Ganges.

BRADFORD ROYAL INFIRMARY.

THREE CASES OF MYELOID LEUKÆMIA.

(Under the care of Dr. H. J. CAMPBELL.)

FOR the notes of the cases we are indebted to Dr. A. W. Falconer, house physician.

CASE 1.—A man, aged 26 years, was admitted to the Bradford Royal Infirmary on March 28th, 1906, under the care of Dr. H. J. Campbell. For some weeks he had not been feeling well and had been treated by his medical man for debility. A fortnight before admission he was suddenly seized with severe pain in the back of the head and dizziness. He had to go to bed on account of the pain and in the course of a few days he became quite deaf and was unable to walk on account of staggering. After the first day the pain in the head left him. He had no vomiting. There was no history of any hæmorrhages or of pain in the abdomen. On admission the temperature was 100° F., the pulse was 100, and the respirations were 20. He was a fairly nourished man, not markedly anæmic, and his mental condition was quite bright, but he was absolutely deaf. There were a few of the inguinal glands as large as peas and one or two of the cervical glands were also palpable. There were no tenderness over the sternum or the long bones and no skin changes. With regard to the abdomen there was splenic dulness in the nipple line from the sixth rib to the level of the umbilicus. Anteriorly the spleen extended to within two inches of the umbilicus and posteriorly filled the left lumbar region. It was quite smooth and hard, not tender, and moved freely between the hands. The liver dulness extended from the sixth rib to two inches below the costal margin in the nipple line. It was quite smooth and not tender. As to the mouth, the tonsils were not enlarged and the mucous membrane was normal. With regard to the nervous system, the cranial nerves, with the exception of the second and eighth, were normal. There was intense double optic neuritis in both eyes; the swelling of the right disc was + 7 and of the left + 6 dioptres. In both macular regions were several small greyish-white more or less circular patches about one-sixth of the size of the optic disc. These were not raised and had a peculiar half-veiled appearance. In the periphery of both fundi were numerous dead white patches, many of them larger than the disc. They had a granular appearance and were distinctly raised, covering in many places the retinal vessels. There were also numerous hæmorrhages throughout both fundi. Hearing was quite absent in both ears. There was no bone conduction but some tinnitus. As to the limbs there was no paralysis or rigidity; the superficial, deep, and organic reflexes were normal, and sensation was normal. The gait was very markedly staggering, the patient being unable to walk alone. He seemed to have had more tendency to fall to the right than to the left. The heart, the lungs, and the urine were normal. An examination of the blood showed: hæmoglobin, 50 per cent.; red cells 2,350,000 and white cells 845,000 per cubic millimetre; myelocytes, 56·4 per cent.; polymorphonuclear neutrophiles, 38·2 per cent.; eosinophiles, 4·4 per cent.; lymphocytes, 0·8 per cent.; mast cells, 0·2 per cent.; and there were numerous nucleated red cells. On the second day after admission the temperature fell and remained normal till the fourth day, when the patient became aphasic and died within an hour. No post-mortem examination was obtained.

CASE 2.—A boy, aged six years, was admitted to the Bradford Royal Infirmary on March 22nd, 1906, under the care of Dr. Campbell. The patient had not been well for some months. He had no definite pain but did not care to run about. He had been attended by a medical man for six weeks for anæmia. There was no history of any hæmorrhages. He was a poorly nourished boy and was very markedly anæmic. There were numerous small glands in both inguinal regions and in the cervical regions on both sides. The glands were of about the size of small peas, moderately hard, discrete, freely moveable, and not tender; there was no tenderness of the sternum or of the long bones. The spleen was enormous. The dulness began in the nipple line at the sixth rib and extended into the abdomen, crossing the middle line one inch above the umbilicus and extending one and a half inches to the right of the middle line at the level of the umbilicus. From there it curved down to the left to the pubes and seemed to extend into the pelvis. Posteriorly it filled the whole left lumbar and inguinal regions. The liver extended half an inch below the costal margin. The nervous system was normal. The fundus oculi was normal There were hæmic murmurs at the base and the apex of the heart. A blood count on March 29th showed: hæmoglobin, 45 per cent.; red cells 2,260,000 and white cells 146 970 per cubic millimetre; myelocytes, 36 per cent.; polymorphonuclear neutrophiles, 47 per cent.; eosinophiles, 5 per cent.; lymphocytes, 2 per cent.; and mast cells, 10 per cent There were a fair number of nucleated red cells. Another count on April 6th showed: hæmoglobin, 45 per cent; red cells 2.220,000 and white cells 71.871 per cubic millimetre; myelocytes, 38·4 per cent; polymorphonuclear neutrophiles 45·2 per cent.; eosinophiles, 4·4 per cent.; lymphocytes, 4·8 per cent.; and mast cells, 7·2 per cent. The patient only remained a fortnight in hospital when he was taken away by his parents. His temperature rose to between 100° and 101° F. at night and his general condition remained much the same.

CASE 3.—A woman, aged 35 years, was admitted to the Bradford Royal Infirmary on Dec. 9th, 1905, under the care of Dr. Campbell. 12 months before admission the patient noticed a swelling in the left side. In May of this year she was an in-patient at the hospital with myeloid leukæmia. She remained in until July and was treated with the x rays. During the treatment the spleen, which extended below the umbilicus, rapidly disappeared till it could not be palpated. The blood condition showed little change. After leaving hospital the patient felt fairly well, but after about two months the spleen began to grow again. On admission the patient was found to be fairly nourished. There were no enlarged glands felt; the spleen extended to the umbilicus and to within one inch of the anterior superior iliac spine. An examination of the blood on Dec. 15th, 1905, showed: hæmoglobin, 45 per cent.; red cells 3,486,000 and white cells 191,666 per cubic millimetre; myelocytes, 35·9 per cent.; polymorphonuclear neutrophiles, 60·3 per cent.; eosinophiles, 1·5 per cent.; mast cells, 0·8 per cent.; and lymphocytes, 2·5 per cent. The patient was exposed to the x rays over the splenic region for ten minutes three times a week. She was treated for three months and at the end of that time she went home *in statu quo*, the spleen not having diminished and the blood count being: hæmoglobin, 40 per cent.; red cells 3,800,000 and white cells 196,875 per cubic millimetre.

Remarks by Dr. FALCONER.—It seems justifiable to call Case 1 a case of true acute myeloid leukæmia. There was no history of any discomfort for more than six weeks before the fatal issue. The size of the spleen is, perhaps, somewhat against it, but though it extended to the level of the umbilicus it was not a very large spleen, most of the enlargement being downwards and not nearly to the same extent transversely. The nervous symptoms resembling Ménière's disease are also uncommon in myeloid leukæmia. The occurrence of definitely raised white spots in the retina according to Lazarus,[1] though not infrequent in lymphatic leukæmia, has not yet been described in myeloid leukæmia. The blood was that of typical myeloid leukæmia except that the percentage of mast cells was rather low. Case 2, of myeloid leukæmia in a child, is also extremely rare, there being only six cases in the literature. It presented no features differing from myeloid leukæmia in the adult. I am indebted to Dr. Campbell for permission to publish these cases.

Medical Societies.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Achondroplasia.

A MEETING of this society was held on May 8th, Mr. J. WARRINGTON HAWARD, the President, being in the chair.

Dr. GUTHRIE RANKIN and Mr. ERNEST O. MACKAY, in a paper on Achondroplasia, said that the disease, though comparatively recently recognised, was of ancient origin. Mr. George Pernet had pointed out its illustration in the Egyptian statues of the British Museum, notably the god Ptah, and Charcot and Richet had shown that the dwarfs of Philip IV., painted by Velasquez, were probably achondroplasiacs. It had escaped notice largely because most children suffering from the disease were stillborn or did not long survive birth. The survivors were formerly looked upon as examples of either cretinism or rickets. The earliest record was Sömmering's case, published in 1791, which he left unclassified. Busch in 1836 published a second which he called congenital rachitis. But it was the observations of Müller, published in 1860, which showed that the disease was one of primordial bone cartilage and that the inhibition of the growth of the long bones, one of its prominent characteristics, was due to a disturbance of the normal arrangement in rows of the proliferating cartilage cells. The early confusion with "fœtal" rickets was traced in the papers of Shattock, Barlow, and others, and was illustrated by a reproduction of an engraving in Liston's "Surgery," published in 1840 of a skeleton which exhibited the distinctive landmarks of achondroplasia and which the author referred to as a "curious case of congenital rickets." The general appearance of an achondroplasic child was characteristic. He was a dwarf, with large head, pug-shaped nose, short and often bowed limbs, a prominent abdomen, and marked lordosis. The figure was stunted by shortening of the legs out of proportion to the size of the trunk. The arms were also short and the finger tips never reached the level of the hips. The limbs, besides being short, were usually bent and deformed. The central point of the body was above the umbilicus and might be as high as the ensiform cartilage. The abnormal size of the head was caused by undue development of the vault of the cranium There were recession of the base of the nose and prognathus, produced by premature synostosis of the basilar and sphenoid bones, giving rise to deficiency in length of the base of the skull. The lips and eyelids were thickened and, from excess of subcutaneous tissues, there was exaggeration of natural dermal folds. The tongue might be enlarged and protruding. The hair and skin were natural. The fingers and toes were short and spatulate. The hands were fore-shortened and fat with fingers of equal length which tapered to their extremities and separated at the middle phalangeal joints, especially the middle and ring fingers. The shortened bones were thickened transversely and more or less enlarged at their ends, but the change seemed to arise in the diaphyses rather than the epiphyses, which were altered in some cases only. The bones formed in membrane or developed from cartilage late in uterine life were unaffected. The mental faculties remained unimpaired. The etiology was uncertain; it had been attributed to syphilis, heredity, and consanguinity of the parents—all on insufficient evidence. It was an early "disturbance of metabolism in some unknown way." Calcification proceeded normally, as did periosteal bone formation, but growth in length might be interfered with or stopped by a periosteal inclusion attributed to an "outgrowth of the epiphysis beyond the peripheral diaphysial line, causing an involution of periosteum, which subsequently proliferates" The stunted long bones, the shape of the hands, the lordosis, the sunken nose, the high mid-point of the body, and the congenital origin were leading features of achondroplasia distinguishing it from rickets. In cretinism the mental feebleness, vacant expression, vicious habits, and trophic changes of skin and hair were all differentiating features.

---

[1] Nothnagel's Practice of Medicine, American edition, 1905.

Dr. HOWARD H. TOOTH said that he did not think the term "lordosis" should be applied to the deformity present in the patient exhibited; the buttocks were unduly prominent and there was a hollow immediately above them, but the back and spine were quite straight and showed no true lordosis.

The PRESIDENT pointed out that the spine in the skeleton shown in the reproduction of the engraving was quite straight and he thought that the apparent lordosis was due to two factors: first, to the tilting of the pelvis, and secondly, to the protuberant abdomen which was due to the flaccidity of the abdominal muscles. He considered it probable that there was a rickety condition added to a congenital deformity.

Mr. STEPHEN PAGET did not think that the nasal bones were deficient and was of opinion that the flattening of the nose was not more than might be seen in normally developed children. Arrested growth of the nasal bones was not uncommon in children and gave rise to a pug shaped nose.

Dr. RANKIN replied.

OBSTETRICAL SOCIETY OF LONDON.

Epithelioma of the Vulva.—Laminaria Tents.—Exhibition of Specimens.

A MEETING of this society was held on May 2nd, Dr. W. R Dakin, the President, being in the chair.

A short communication on Three Cases of Epithelioma of the Vulva with the history subsequently to operation was read by Dr. A. H. N. LEWERS: 1. A multipara, aged 47 years, had a malignant growth—squamous carcinoma—removed from the right side of the vulva on Dec 7th, 1896, and the glands in the right groin were removed at the same time. A small growth reappeared on the left side of the vulva about two years later and was removed in December, 1898. In January, 1899, the glands in the left groin were removed. A small growth reappeared on the left side of the vulva and was removed on March 9th, 1901. Since that time the patient had remained quite well. She was examined and found free from recurrence on March 8th, 1906—over nine years since the first operation and almost exactly five years since the date of her fourth and last operation. 2. A multipara, aged 52 years, had a malignant growth—squamous carcinoma—of the clitoris removed on Sept. 1st, 1899. The glands were at the same time removed from both groins. The patient was known to be well and free from recurrence on March 11th, 1906. 3. A multipara, aged 34 years, was operated on for a malignant growth—squamous carcinoma—of the vulva on March 31st, 1905. She was eight months pregnant at the time. Labour came on four days later and she was delivered naturally of a living child. On May 4th the glands in both groins were removed. The disease rapidly recurred in the same place and the growth was again removed on June 20th. The growth again recurred soon afterwards and she underwent the x ray treatment from August 11th to Sept. 9th without benefit. She died about three months afterwards. Attention was directed to the fact that local recurrence in cases of epithelioma of the vulva was not necessarily of unfavourable significance, as illustrated in the first case. Case 3 was remarkable in being an example of epithelioma of the vulva occurring in a patient no more than 34 years of age and in being complicated by pregnancy. In this case the growth ran an exceedingly rapid course, which might possibly have been due partly to the pregnancy and partly to the fact that the patient was only 34 years of age; Dr. Lewers considered that removal of the growth by Paquelin's cautery was a better method than removal by the knife. The specimens from Cases 1 and 2, in which the disease did not recur, together with sections of the growth, were exhibited.—Mrs. STANLEY BOYD referred to cases on which she had operated for epithelioma of the vulva in which 11 and nine years had elapsed without recurrence after a second operation. She preferred removal of the growth by the knife, with suture, to Paquelin's cautery.—Dr. HERBERT R. SPENCER referred to cases that he had operated on, one remaining well for eight and a half years and another for three years. In another case several operations had been performed and the patient now, 13 years after the first operation, had recurrence in the pelvic glands. He advocated removing the whole of the vulva in order to get rid of the leukoplakial skin.—Dr. J. INGLIS PARSONS having advocated removal by the cautery, Dr. LEWERS replied.

Sir WILLIAM J. SINCLAIR then gave a demonstration on the Use of Laminaria Tents. He showed a large number of specimens of the material from which the tents were made, illustrating the various stages in their manufacture. The specimens of laminaria exhibited were obtained from islands on the West Coast of Scotland, from Coll and Iona and others. He considered the laminaria from the district mentioned was superior to that hitherto in the market. He had observed with regret how much the use of laminaria tents for dilating the cervix had gone out of fashion, as he considered dilatation by the use of tents far superior to that obtained by the use of rapid dilators. Very serious results were liable to be produced by rapid mechanical dilatation, more especially in the hands of those with little gynæcological experience.—Dr. HEYWOOD SMITH said that larger tents were made by pegging together sections of the material, a process which might cause irregular dilatation or even lead to breaking up of the tent. He was glad to see from the specimens shown that it would be possible to obtain tents as large as could be wanted in a single piece.—Dr. AMAND J. M. ROUTH had had an opportunity of testing the tents and had found them quite as good as those sold in London.—Dr. R. BOXALL remarked that the main objection offered to the use of tents was the inherent possibility of infection, but by dry heat laminaria tents could be not only sterilised but improved in quality, a process which could be accomplished, if necessary, in the domestic oven.—Dr. G E. HERMAN did not think laminaria was as much out of fashion as Sir William Sinclair supposed. It had been used for 30 years or more in the London Hospital. He did not like tents made of several pieces of laminaria glued together, for the glue was very possibly septic He was surprised to hear anyone say that the dilating force of laminaria was weak, for Matthews Duncan had shown that laminaria was capable of exerting a force of 640 pounds to the square inch.—Dr. PARSONS thought that, on the whole, dilatation with metal dilators was preferable to dilatation by tents —Mr. W. GANDY said that some years ago he used nothing else but tents to dilate the cervix and he felt that with ordinary care no harm could befall the patient.—Dr. Spencer was surprised at Sir William Sinclair's statement that laminaria tents had gone out of fashion. They had been used continuously at University College Hospital for the last 25 years. He could not imagine that any gynæcologist would dilate a rigid senile cervix in order to explore it with the finger by rapid dilatation.—Dr. Lewers said that it was important to bear in mind the degree of dilatation of the cervix required in choosing between dilatation by the rapid method or dilatation by laminaria tents. In many cases it was certainly impossible to dilate the cervix sufficiently to allow of the introduction of the finger into the uterus by the rapid method without causing laceration. It had to be borne in mind that when a laceration occurred it could not be limited in any way at the will of the operator. It might be a slight and unimportant laceration or it might extend right through the uterus into the broad ligament or peritoneal cavity. As a rule, Dr. Lewers used tents the day before he required exploration, and then, under an anæsthetic, if necessary passed a few sizes of Hegar's bougies.

Dr. Lewers showed two specimens of Large Uterine Fibroids undergoing necrobiosis, or red degeneration

Dr. F. J. McCann showed (1) Cervical Fibroid; (2) Broad Ligament Cyst with torsion of the pedicle; (3) Primary Cancer of the Vagina; and (4) Sarcoma of the Vagina.

Dr. W. W. H. Tate showed a large Fibroid.

Dr. Parsons exhibited a Fibro-myoma of the Vulva in an unusual position.

HUNTERIAN SOCIETY.

Discussion on Syphilis.

A meeting of this society was held on April 11th, Mr. John Poland being in the chair.

Mr. Jonathan Hutchinson opened the discussion with a reference to the mortality from syphilis. This reached a maximum in 1875—viz., 2140, against 1834 in 1904, although allowing for increase of population the figure should be 3000. Not only was the disease on the decline but it was generally considered to be milder in type as a result of more effectual treatment. Judd and his followers (1835–38) obtained excellent results without mercury, using iodide of potassium, but the use of this drug securely established the mercurial treatment and led to a better knowledge of the precise uses of both of them. A century since all venereal sores were treated by mercury. When the non-syphilitic nature of many such sores was recognised mercury was withheld until secondary symptoms were manifested, and this period of withholding mercury coincided with the increased mortality. Lastly, when the small dose plan was introduced, mercury was robbed of its terrors and was employed at the earliest moment with a view to the suppression of the secondary stage. Ptyalism is objectionable and injurious. As much mercury as can be borne should be introduced into the blood. Everything that mercury could do could be conveniently effected by the one grain grey powder pill with Dover's powder taken from three to seven times daily. Mr. Hutchinson advanced the following propositions. 1. It was now almost universally acknowledged that mercury ought invariably to be given in the primary and secondary stages of syphilis. 2. That the earlier it was begun the better, provided the diagnosis be certain. 3. That it was possible to prevent entirely and to anticipate the secondary symptoms, an opinion which he had advocated for 25 years. 4. That the suppression of the secondary stage to a large extent prevented tertiary symptoms which were developed in the actual site of the secondary manifestations. 5. That many chancres were sufficiently characterised to justify immediate treatment. 6. That as much mercury should be given as the patient could bear, avoiding diarrhœa and ptyalism. 7. That continuous treatment was much preferable and should extend over at least 12 months. 8. That at this stage the object was to kill the parasite. In the tertiary stage the destruction of the parasite was no longer the object of treatment. Tertiary changes were often single, very rarely indeed general, often restricted to one organ or one tissue, and there was no reason to regard them as of blood origin, whether toxic or otherwise. The parasite was, in fact, no longer existent. 9. That tertiary symptoms were commonest where early treatment had been delayed or inadequate. 10. That there was good reason to believe that syphilis was becoming less prevalent and less severe in Britain and that this was largely due to the widespread adoption of the long-continued and small-dose method of treatment. 11. That the inunction and calomel vapour-bath methods were both efficacious but inconvenient and expensive and liable to be prematurely discontinued. 12. That intramuscular injections were very dangerous, excepting in the hands of the expert, and should be wholly reserved for special conditions, chiefly in the army. If salivation commenced it could not be stopped except by the excision of the portion of muscle containing the mercury. 13. That tertiary symptoms were (*a*) inflammatory; (*b*) degenerative; or (*c*) gummatous; and that the iodide of potassium internally, and iodoform, iodol, and chinosol externally, were specifics and often produced permanent cure of gummatous growths. Degenerative changes such as tabes were, on the other hand, rarely arrested by specifics. All conditions attended by inflammatory changes, such as general paralysis of the insane, should be treated by small doses of mercury continued permanently. In his belief, if treatment of general paralysis were commenced in the very early stage, a cure might be obtained, but small doses of mercury must be permanently continued. 14. Tuberculosis sometimes complicated tertiary syphilis. Syphilitic lupus was a combination of the two and some "relapsed chancres" were tuberculous. 15. With reference to marriage, if the treatment had been continued for two years from the date of the chancre, a man might safely marry, but a much longer period was necessary for a woman. 16. As regards inheritance a man with tertiary symptoms might have quite healthy children. Syphilis could not be transmitted to the third generation. The fact that younger children in syphilitic families were free from the syphilitic taint and were well grown and robust was opposed to the belief that the disease, when incapable of transmitting its characteristic symptoms, might still cause arrest of development. Nor was syphilis an appreciable cause of degeneracy of the race. The Fijians, who had had syphilitic frambœsia from time immemorial, were not a degenerate race. Mr. Hutchinson concluded by mentioning a supposed fact for which he knew no explanation. Why was syphilitic infantile iritis, and to a less degree keratitis, more common in female infants than in males? They knew little of differences in the character of the disease as affected by sex and by inheritance from the father as compared with the mother.

Dr. G. H. Savage mentioned, first, the occasional occurrence of acute mania in syphilitic fever, as in alcoholism and influenza. With reference to the effects of syphilis on neurotic and non neurotic persons statistics showed that the former were liable to tabes whilst the general paretics were, as a rule, non-neurotic. Dr. Savage agreed with Mr. Hutchinson that treatment had altered the character of syphilis. Gummata had become comparatively rare in post-mortem experience. On the other hand, there was a certain number of cases of acute mental disorder, associated with cranial nerve symptoms, hemiplegia, or epilepsy, which followed acute syphilis and which might possibly depend upon a gumma. More chronic mental disorders, with similar local manifestations, might also result from syphilis. Some went on to general paralysis of the insane which under Mr. Hutchinson's continuous treatment might not occur. Many cases of general paralysis showed an early history of temporary aphasia or monoplegia which were forgotten after perhaps brief treatment by iodides. Early syphilitic changes might affect any part of the nervous system. There was also a more general and diffuse disorder of the cortex associated with syphilis. For example, cases of marked hysteria in middle-aged men who had had syphilis in former years, although they might temporarily recover, usually end in general paralysis. A large number of general paralytics with a syphilitic history commenced as ataxics, the ataxy preceding the paralysis by some years. Progressive mental degeneration might be associated with syphilitic endarteritis. The nutrition of any part of the brain might be interfered with, with alteration in the balance of mind, ending invariably in dementia. Dr. Savage pointed out that the memory was not markedly affected in these cases; sometimes, as in advanced stages of general paralysis, there was a quite remarkable retention of memory, whilst in other forms of progressive mental decay, associated with alcoholism or senility, the loss of memory was the chief characteristic. With reference to the causation of general paralysis, it had been pointed out that among certain races—the Arabs and perhaps the Japanese—syphilis might be prevalent and general paralysis very rare. It was also said to be unknown amongst.

Negroes and amongst the Irish. In Dr. Savage's opinion syphilis required something more in order to produce this disease, alcoholism, worry and the stress of life, and perhaps large meat-eating. Fewer women than men were affected. It rarely came on within ten or 12 years, more frequently between 15 and 20 years after primary infection. Mental symptoms, insane interpretations, might also be associated with syphilitic locomotor ataxy. On the psychical side, Dr. Savage referred to syphilophobia of adolescents and the more dangerous syphilitic hypochondriasis of middle aged and older men. In the latter condition the patient might have some "stigmata" of old syphilis, giving rise to various beliefs and delusions. One class of patients believed themselves to be shunned or insulted. These were often suicidal. Others believed themselves centres of contagion and were intensely suicidal or homicidal.

Dr Purves Stewart pointed out that in many cases syphilis of the central nervous system was, so to speak, accidental and affected the non-nervous tissues and only secondarily the nerve elements. Thromboses, aneurysms, and gummata did not spring from nerve tissue, although the symptoms were nervous. This class of disease was not at all confined to the tertiary period but might occur at any stage, even when the chancre was still present. In another class of syphilitic nerve disease the nerve elements underwent primary dystrophy with production of sclerosis, which was a secondary change. Syphilitic spastic paraplegia, in which the bladder symptoms were prominent, might belong to this class. This often developed within a year of infection. Tabes and general paralysis might be regarded as two varieties of one disease, a syphilitic affection of nerve elements. Dr. Stewart then described the results of his own observations on the cerebrospinal fluid. A microscopic field from centrifugalised normal fluid contained perhaps one or two endothelial cells and as many leucocytes. In functional nervous diseases, in epilepsy, paralysis agitans, and disseminated sclerosis the cerebro-spinal fluid was apparently normal. With organic diseases of the nervous system, acute microbic meningeal affections, and suppurative diseases of brain or membranes, the fluid contained polynuclear leucocytes. In the case of chronic nervous affections, tuberculous and syphilitic, there was always great excess of lymphocytes, usually monomorphic. In syphilis without nervous affection there was no excess. In gummatous affections of the nerve centres the excess was marked but in tabes and general paralysis the leucocytosis was constant and extremely well marked, the average being 130 to the field. The presence of leucocytosis was of great diagnostic importance, for example, as between tabes and peripheral neuritis and between general paralysis and epilepsy. In order to exclude syphilis of the nervous centres it was not necessary now to suspend judgment pending the use of iodide and mercury.

Dr. W. Hale White said that our knowledge of visceral syphilis dated from the paper of Sir Samuel Wilks in 1863. It was an interesting fact that, with the possible exception of the heart, syphilitic endarteritis in the viscera was not of any clinical importance and was, in fact, not met with, which was in striking contrast to its great importance in the nerve centres. Another syphilitic affection of the viscera—lardaceous disease—was now much less frequently met with, as a result of improved surgery and also, no doubt, of the declining severity of syphilis. Congenital syphilis occasionally produced marked lardaceous disease. In syphilitic laryngitis specific treatment was often useless unless the part was rested by tracheotomy. Abductor paralysis might be the earliest indication of tabes. Syphilitic ulceration or stenosis of the trachea might be met with apart from laryngeal affection and usually occurred near its bifurcation with impaired entry of air in one lung. Syphilis of the lungs was excessively rare and the diagnosis was not justified. The frequency of congenital syphilis of the lungs had been enormously exaggerated. No museum in London contained a specimen of it and he doubted if such a condition existed. The acquisition of syphilis usually greatly accelerated phthisis, whilst it was also true that a syphilitic patient was more liable to phthisis than others. In the heart gummata were rare and the diagnosis a bold one. The late Dr. C. H. Fagge had shown that a large proportion of the cases of fibroid disease of the heart were syphilitic, and that there was a peculiar liability to sudden death in this affection. Since Dr. Fagge's paper in 1874, 11 cases of sudden death due to this disease had been recorded at Guy's H [illegible] f which five were syphilitic. The fibrosis sh [illegible] for in the inter-ventricular septum. With reference to valvular disease he (Dr. Hale White) held that the aortic valves were rarely affected alone in rheumatism. Therefore cases of aortic without mitral disease might be attributed to atheroma, or strain, or syphilis; and in women, as strain was rare, aortic disease was strong evidence of syphilis. The same applied to aneurysm. Dysphagia was sometimes due to syphilitic ulceration of the pharynx or the œsophagus. Gummata were almost unknown in the stomach and intestines, but syphilitic ulceration and stricture occasionally occurred in the rectum in women, with symptoms of chronic obstruction. In the liver syphilis occurred as gummata or fibrous bands but was far less common than formerly. It was never accompanied by jaundice. In syphilis the liver was seldom so large and uneven, and seldom increased in size so rapidly as in malignant disease. Congenital syphilis produced a similar condition. He agreed with Mr. Hutchinson that the largest gummata of the liver were curable. That was about the only form of visceral syphilis in which a diagnosis was commonly made, because the other conditions were so rare.

Dr. Hale White exhibited a beautiful selection of specimens from the Guy's Hospital museum illustrating the various conditions which he had described.

Mr. T. P. Beddoes said that the essential factor in the Zittman treatment appeared to be heat, the patient being kept in a small room at 80° F., and connected this fact with the slight incidence of tabes and general paralysis in hot countries. He doubted whether alcohol had much part in the causation of the latter diseases as there seemed to be no difference in their occurrence in Turkey, where many of the population were teetotalers, and in Brazil where there was much alcoholic excess. Both Brazil and Turkey have much syphilis and in both countries tabes and general paralysis are extremely rare.

The adjourned discussion was continued on April 25th, Dr. F. J. Smith, the President, being in the chair.

Dr. Theodore Shennan described and demonstrated Spirochætæ in Syphilitic Lesions. Two spirochætæ were found commonly in the lesions of primary and secondary syphilis—viz., the spirochæta pallida, which many thought was the cause of syphilis, and the spirochæta refringens, which was specially found in ulcerated lesions and had already been described as a saprophyte in various secretions and tissues. The spirochæta pallida was more delicate than refringens, possessed closer spirals, showed more motility, and was more difficult to detect and to demonstrate. It had been found in congenital syphilis, in the organs and blood, as well as in the acquired disease, but, according to most observers, never elsewhere and never in tertiary syphilis. It was also found in experimental syphilis in the monkey. Certain loop-shaped bodies which seemed to have some relationship to the development of a spirochæta form were then described. These were to be found commonly in skin lesions and in indurated buboes. Dr. Shennan concluded with a lantern-slide demonstration and showed microscopical specimens with the parasite *in situ*.

Dr. G. F. Still alluded to the occasional occurrence of acquired syphilis in children, which had been stated to be highly contagious. Contrary to the opinion of some recent writers, he held that the risk of contagion from the inherited disease was very small. Among a large number of children he had never known one case of infection, although such cases had been reported and the spirochæta had been found in the bullæ of syphilitic pemphigus of the newly born. In addition to the very considerable mortality from stillbirth and miscarriage, there was incapacity in the survivors, from keratitis, iritis, and nerve affections. As many as 10 per cent. of the children showed some nervous affection. A large proportion of idiots were, in Dr. Still's opinion, syphilitic and some children with inherited syphilis, at first bright and intelligent, showed mental deterioration in the second period of life, between six and 12 years of age, became dull and perhaps epileptic and demented, sometimes greatly emaciated and dying from exhaustion. In these cases chronic meningitis and extensive sclerosis of the cortex were found. A proportion of congenital hydrocephalus, of paraplegias and diplegias was also due to congenital syphilis and the same cause accounted for many cases of fatal convulsions, and perhaps epilepsy. In certain families the nervous tissues, viscera, or bones would appear to be especially liable whether to tuberculosis or to syphilis. The undesirable term "parasyphilitic" was founded on the very doubtful theory that a non transmitted syphilis had influenced development and implied a specific origin which

d not only by constitutional changes but also by alteration in the physical signs. As a proof of local in pulmonary tuberculosis he observed that in chronic ior to inoculation the bacilli were extracellular while oculations phagocytosis could be seen. He pointed t possibly watching the phagocytic index in the sputum e used as a general guide for inoculation. In acute ary tuberculosis phagocytosis in the sputum was n. He held that tuberculin treatment in selected cases e practised in conjunction with sanatorium methods.—ES BARR related the case of a young woman who had der the care of Dr. Blair Bell and himself. She was g from infective endocarditis of a very severe type streptococcal infection. A rigor occurred every rs or oftener, during which the temperature ran up or 105° F. and was followed by profuse sweating. was an attack of pleurisy with pleuro-pericardial but without any marked effusion. All the various of antistreptococcal serum had been tried without enefit. The assistance of Professor A. E. Wright ptain S. R. Douglas was obtained and a vaccine was rom the streptococci obtained from the patient's own Captain Douglas estimated her opsonic power twice nd by him the injection of the vaccine was regulated. ally the patient made an excellent recovery and, he exception of the effects of phlebitis of the left limb, she was now quite well. Sir James Barr ted the success of the case to the vaccine, and id a high compliment to the dexterity and lative skill of Captain Douglas.—Dr. W. B. NGTON alluded to the statement of Professor Wright, d by Dr. Bradshaw, that local lesions did not tend to eous recovery. Dr. Warrington asked whether the y of local tuberculous lesions of the lungs and e was not notably towards recovery. It had been that though marked improvement might be noted in ulmonary tuberculosis yet the opsonic index remained r. Crace-Calvert asserted the contrary. These state- equired verification. Assuming that the index was in- by general treatment should tuberculin be adminis- Many, no doubt, would feel a difficulty in accepting planation of badly adjusted and ill-spaced auto- tions to explain the high opsonic index in the more cases; though fluctuating, it seemed in many cases ain above the normal. Dr. Warrington considered e related by Sir James Barr of great value and one showed the value of the vaccine treatment as opposed t of antibacterial sera The latter had proved of alue in his practice.—Dr. G. A. CRACE-CALVERT, Dr. N RAW, Dr. YORKE, Dr. W. O. ORAM, and Professor also took part in the discussion.—In replying, Dr. HAW said that none of the speakers who had any nce of the method had controverted the main points paper. He was inclined to attribute the remarkable of the anti-sera to a specific influence immanent in od of the horse.

ASGOW MEDICO-CHIRURGICAL SOCIETY.—A g of this society was held on April 20th, Dr. L. y Steven, the President, being in the chair.—Mr. J. h Pringle showed: 1. Two cases operated on for Osteomyelitis. In the first the lower epiphysis of the was separated from the diaphysis, and the upper sis was involved centrally. The whole diaphysis was d and the bone was now almost completely remodeled. second case the disease was thought at first to affect ine of the scapula only. Later the shoulder-joint e affected and as the scapula was surrounded with pus removed with the head of the humerus. In four s the scapula became re-formed. 2. A case of "Black e"—hypertrophy of the papillæ with pigmentation. ts to grow an organism failed. 3. An almost com- remodeled Femur after removal of the diaphysis he lower epiphysis to the small trochanter. The limb be amputated on account of persistent non-union after e. 4. A "Grawitz" Tumour of the Kidney. After months' hæmaturia the kidney had been removed. ns of the tumour shown resembled the cortical part suprarenal bodies. Grawitz believed the tumour ise from suprarenal inclusions.—Mr. Archibald showed, with the kind permission of Mr. G. H. s, two cases of Arterio-Venous Aneurysm follow- wounds in which spontaneous cure was taking place. The first case was that of a man wounded at the Modder, in whom there were symptoms originally of an aneurysmal varix of the right innominate vessels. Within four days of the injury a limited pulsating swelling had begun to develop, accompanied by a strongly marked thrill and systolic bruit. 25 days after injury the thrill was even more marked and a typical "machinery murmur" had appeared. A year later Mr. Makins found the condition much improved, the patient was at work as a lamp trimmer, but had some dyspnœa on exertion. The right pupil was dilated. Thrill and "machinery murmur" were much less obvious. There was now practically no pulsation, the thrill and murmur had practically disappeared, and there was no tumour to speak of. The man was able to do his work and had little or no trouble of any kind related to the original lesion. Distension of superficial veins (especially of the external jugular noted a year ago) had virtually disappeared. It might be said that the cure was, in this case, almost complete; all evidence of venous communication had disappeared and there was very little sign of arterial enlargement. The right pupil still remained, however, larger than the left. The second case was that of a man wounded at Magersfontein in whom the symptoms pointed to an arterio-venous (varicose) aneurysm at the root of the right carotid artery. Originally there was a large pulsatile swelling about the right sterno-clavicular joint and extending upwards beneath the sterno-mastoid muscle, backwards into the posterior triangle, and downwards behind the clavicle and upper ribs. The wall of the aneurysm was at first thin and yielding. Purring thrill and "machinery murmur" were strikingly developed and widely distributed. Evidence of damage to the ulnar nerve also existed. Seen by Mr. Makins a year later, the aneurysmal sac had undergone considerable consolidation and the wall had become dense and firm. Thrill and murmur, though still present, had become more localised. The ulnar nerve symptoms persisted. There was much dyspnœa on exertion and the man was not fit for work. Now the aneurysmal swelling, though still present, was distinctly smaller. Pulsation was less. The thrill and murmur had practically gone. Dyspnœa on exertion was much less marked and the man was in steady employment, driving a van for from four to five hours on six days in the week. There was evidence of secondary involvement of probably all the elements of the brachial plexus on the right side—weakness of all the arm and forearm muscles—but specially of those supplied by the ulnar nerve. Improvement in the arterio-venous lesion, however, was such that the man lived a comfortable life and there was now practically no evidence of venous disturbance. The lesion which still persisted might be regarded as a purely arterial one.—Dr. A. N. McGregor gave the clinical history of a case of Sarcoma of the Femur treated by Amputation through the Hip. The patient was a man, aged 30 years. The tumour had been growing for nine months and was quite free from pain. There was no history of injury. The tumour was of the size of an orange and occupied the popliteal space, bulging out on the inner aspect of the thigh. Locomotion, &c., were interfered with solely on account of its bulk. Amputation through the hip-joint was performed and he made an uninterrupted recovery.—Dr. James Scott showed the specimen with microscopic preparations. Section of the bone antero-posteriorly in the transverse plane showed that the medulla had been invaded. There was no expansion of the bone centrally. The tumour mass outside the bone was composed of spindle cells but within the bone a few distinct giant cells were seen in places.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on May 4th, Mr. L. A. Bidwell, the President, being in the chair.—An instructive discussion took place on the Varieties and Sequelæ of Influenza.—Dr. Seymour Taylor, in opening the discussion, said that in his view the multifarious forms which attacks of influenza took were mainly due to the differing soils which the micro-organism found in different patients. He was accustomed to group the cases under five types—namely, the neurotic, the pulmonary, the circulatory, the febrile, and the gastro-intestinal. The sequelæ, he thought, were, at least in some cases, dependent on a mixed infection and any constitutionally weak spot in a patient was particularly liable to be the one affected.—The President remarked that so far as his experience went particular epidemics seemed to be characterised by special types of the disease; he was especially interested in those cases in which acute abdominal disorder was sometimes very closely simulated; he also spoke of those cases in which bone or joint disease might follow as a sequela; probably these were due to secondary infection.—Dr. E. Arthur Saunders agreed with Mr. Bidwell that varying types occurred in different epidemics. One of the most serious sequelæ in his experience was severe cardiac depression which was generally accompanied with a very slow pulse, which might also be intermittent; the danger of syncope in such a condition was very great. In his opinion this state was due in part to affection of the vagus and in part to a toxin directly acting on the heart muscle. The very marked general depression which was so frequently seen after an attack was, he believed, a combined result produced both from the nervous and circulatory systems.—Dr. F. Rufenacht Walters said that in the sanatorium with which he was connected they saw little influenza and he attributed this to the open-air conditions, for it was a not infrequent trouble in villages in the neighbourhood. No doubt a certain number of cases of pulmonary tuberculosis owed their commencement to this disease and also some cases which were quiescent were reawakened by an attack.—Dr. W. Culver James spoke of certain cases of infective pneumonia which he had seen antecedent to the time of the recrudescence of influenza in an epidemic form in this country; these he now believed to be of influenzal origin.—Dr. Stanley Smith observed that it seemed to him that neuritis of various kinds was much more common since influenza was such a frequent affection and he thought that these diseases were most probably related to one another as cause and effect.—Dr. Leonard O. T. Dobson also referred to the frequency of neuritis, especially of the musculo-spiral nerve. In his experience this trouble was best met by treatment with high frequency electrical currents.—Dr. E. Furniss Potter spoke of the severity of those cases in which the middle ear and then the mastoid became affected, the amount of bone destruction which resulted being often extreme. This trouble was, however, rather a complication than a sequela.—Dr. R. W. Lloyd, Dr. W. A. Bonney, Mr. H. W. Chambers, Dr. A. Kinsey-Morgan, and Dr. F. G. Lloyd having taken part in the debate Dr. Taylor replied.

GLASGOW OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on April 25th, Dr. J. K. Kelly, the President, being in the chair.—Dr. J. M. Munro Kerr showed the following specimens: (1) Multiple Myomata of the Uterus; (2) Tubo-ovarian Cyst; and (3) Chorio-Epithelioma of the Uterus.—Dr. Alexander MacLennan showed the Uterus and Vagina from a case of Complete Procidentia.—The President showed an example of Chorio-epithelioma of the Uterus.—Dr. John Lindsay and Dr. G. N. Turner read notes of a case of Fœtal Malformation. The right knee presented, there being a club-foot on this limb, the other limb being dwarfed and widely separated from its fellow and there being a ventral hernia and malformation of the uro-genital organs. The diagnosis of the position was unusually difficult but the delivery was easy. The malformations found in the infant post mortem were split pelvis, ventral hernia, extroversion of the bladder, split penis and scrotum (the testicles being within the abdomen), persistent cloaca with largely developed Müllerian ducts (cornua uteri masculini), absence of greater part of the colon, and sacral meningocele. The dwarfed limb was destitute of muscles and nerves, there being only fat between the bones and skin. The paper was illustrated by drawings and microscopic slides.—Dr. MacLennan asked whether there were any tendons in the toes.—Dr. Lindsay replied that they were absent.—Dr. John Baird read notes on a case of Parturition in a patient with Double Uterus, Cervix, and Vagina. A septum extended from immediately above the meatus to the centre of the perineum and upwards to the cervix, about one-eighth of an inch in thickness, and completely separating the vagina into two compartments. Two os uteri were felt, the presenting foot being in the left. As labour advanced the septum became detached from the upper part of the vagina, its edge obstructing the advancing head. Dr. Munro Kerr in consultation ligatured and divided the septum and delivered a stillborn child with forceps. Two distinct uteri were made out.—Dr. Munro Kerr and Dr. R. Jardine spoke of similar cases.—Dr. W. A. Caskie read notes on cases of Puerperal Eclampsia and one of Inversion of the Uterus. In the case of inversion of the uterus the patient was seen 12 hours after delivery by a midwife; the uterus was completely inverted and was replaced by means of compression and rotation. Ergot was given as a later treatment.—Dr. Jardine thought the use of ergot dangerous in these cases, as it might cause a return of the condition; in his opinion inversion was seldom caused by pulling on the cord, as the cord would break if much traction were used and it would therefore require a strong cord to bring about inversion of the uterus.—The President, Mr. J. Craig, and Dr. MacLachlan spoke.—Dr. Caskie replied.

Reviews and Notices of Books.

The Diagnosis of Tuberculosis of the Lung, with Special Reference to the Early Stages. By Dr. K. TURBAN, Privy Councillor of the Grand Duchy of Baden; Director of the Sanatorium at Davos. With an Introduction by Sir DYCE DUCKWORTH, M.D. Edin., LL D., F.R.C.P. Lond. Translated by EGBERT C. MORLAND, M.B., B.Sc. Lond. London: John Bale, Sons, and Danielsson, Limited. 1905. Pp. 135. Price 5*s*.

THIS book is a translation of the first two sections of Dr. Turban's "Beiträge zur Kenntnis der Lungen-Tuberculose," published in 1899. In its preparation Dr. Morland has had Dr. Turban's constant co-operation and many additions and corrections have been made, so that the work may be taken as the expression of Dr. Turban's views at the present time. The book actually consists of two originally distinct papers, the one on Early Tuberculosis of the Lung and the Classification of the Disease into "Stadia," and the other on Physical Examination in Tuberculosis of the Lung. No attempt, we think wisely, has been made to combine the two in one essay and the title of the translation may be regarded as a compromise.

The work is divided into three sections, respectively entitled "Early Tuberculosis of the Lung," "Classification of Tuberculosis of the Lung," and "Physical Examination in Tuberculosis of the Lung," thus dividing the first of the papers named above into two parts. Numerous interesting observations are made in the first section on the manner in which pulmonary tuberculosis commences. The question is raised as to whether the physical signs which are so often noted at the apex of the upper lobe of one lung and which are usually regarded as being due to tuberculous infiltration are always to be ascribed to that condition. That certain other conditions may occasionally affect the apex of the lung is, of course, well known but they do not give rise to the collection of physical signs now referred to. As these signs are so frequently met with if they are not due to tubercle some apical disease of a non-tuberculous nature should often be detected at necropsies. Dr. Turban points out that lesions of such a nature are very rarely found, whilst morbid conditions due to tubercle are discovered in one-third, or even one-half, of all post-mortem examinations. He therefore rightly concludes that the apical lesions diagnosed during life as being of a tuberculous origin are in the highest degree of probability of that nature.

Dr. Turban also refers to the insidious manner in which pulmonary tuberculosis develops and the long period which may elapse before breaking down of the lung tissue may occur. When the organism has reacted to the invasion of the bacillus with inflammation and tissue proliferation there may be a pause before softening occurs. This pause may be temporary or permanent and occurs at any rate once in an overwhelming proportion of cases of chronic tuberculosis and often several times in the course of the disease. This state of equilibrium in the damaged organ has been happily termed by French authors "la trêve," a suspension of hostilities. Examples of stationary tuberculosis are frequently seen at necropsies [illegible] who have died from some other cause (accident or disease) than tuberculosis. In many of these cases there have been no symptoms of pulmonary tuberculosis and Dr. Turban suggests that the earliest deposits of tubercle may not necessarily produce clinical phenomena. He argues that whether the disease is manifested early or late depends on the degree of the toxicity of the bacillus, on the production of antitoxins by the organism, and the consequent quicker or slower development of the disease, as well as on its localisation in the bronchi and alveoli or in the interstitial tissue. Most physicians will agree with him that in any case it is false to assume that clinical symptoms must begin, as a rule, with sputum containing bacilli. Bacilli are in general first found in the sputum when foci soften and invade a bronchus, or, to use Dr. Turban's phraseology, "when tuberculosis, until then '*closed*,' becomes 'open.'" This condition is reached sooner or later according to the localisation of the foci and the rate of their development. He further maintains that in cases of pulmonary tuberculosis running a normal course the time during which the "closed" form lasts must be of considerable duration—weeks, months, or years. The symptoms and physical signs of early pulmonary tuberculosis are next discussed in detail and many interesting and instructive points are brought out.

Section II. deals with the division of the disease into "stadia." Dr. Turban's classification is a good one from a clinical point of view and might well be generally adopted for comparative statistics. For those of our readers who are unacquainted with this classification we may state that Dr. Turban distinguishes three stages, or stadia, of chronic pulmonary tuberculosis as follows: (1) disease of slight severity affecting at most one lobe or two half-lobes; (2) disease of slight severity more extensive than in the first stage but affecting at most two lobes, or severe and affecting at most one lobe; and (3) all cases of greater extent and severity than in the second stage.

Section III. describes the physical examination which is required in cases of pulmonary tuberculosis. The various changes which may be noted on percussion and auscultation and the numerous varieties of adventitious sounds which may be heard are well described, and numerous useful hints are given which will be of considerable value to the practitioner in examining cases for the early signs of pulmonary tuberculosis.

We can cordially recommend to our readers a perusal of this little book. It will be found of real practical value and it contains information not included in ordinary text-books on medicine.

The Principles of Treatment and their Applications in Practical Medicine. By J. MITCHELL BRUCE, M.A., LL.D. Aberd., M.D. Lond., F.R.C.P. Lond., Consulting Physician to Charing Cross Hospital and to the Hospital for Consumption, Brompton. Third impression. London and Edinburgh: Young J. Pentland. 1905. Pp. 614.

IN our review of this work when it first appeared[1] we expressed the favourable view that we had formed of it after studying its contents. We explained the nature and scope of the book and commented on the excellent lines on which it was planned. We remarked that it started by assuming no therapeutical laws but proceeded to find them in the familiar facts of etiology, pathological anatomy, and the clinical characters of disease. These points are carefully considered in ascertaining the elementary principles of treatment and in the course of the inquiry the student is taught how he may himself employ his observations as guides to practice. The volume now before us is not a new edition, so that our previous remarks apply equally to this, the "third impression." Dr. Mitchell Bruce states, however, in a prefatory note that advantage has been taken of the demand for a third issue of the work to reconsider and to modify certain opinions and expressions, to introduce some of the newer remedies to the attention of the reader, and to correct a few typographical errors that had previously escaped notice. The fact that two impressions have been so speedily exhausted and that a third has been called for is not a cause for surprise when the reader becomes familiar with the book; it is replete with most valuable information in regard to therapeutics and contains numerous hints which will prove most useful to the practitioner. For speedy reference the second part of the work, "Illustrations of the Principles of Treatment," will be found very serviceable. The treatment of various diseases is considered in detail, but at the end of each chapter a brief summary is given which enables the practitioner or the student to find at once the information desired.

We again have the pleasure of congratulating Dr. Mitchell Bruce on the success of his work which forms one of the most practical and comprehensive manuals in connexion with the treatment of disease which have been published.

Clinical Hæmatology: a Practical Guide to the Examination of the Blood with Reference to Diagnosis. By JOHN C. DA COSTA, jun., M.D. Second edition, revised and enlarged, containing nine full page coloured plates, three charts, and 61 other illustrations. London: Rebman, Limited. 1905. Pp. 591. Price £1 2*s.* 6*d.* net.

WITHIN three years the call for a new edition gives the author of this admirable volume so much to incorporate that he must be glad of the opportunity of crystallising the recent advances at the present time. He indicates three noteworthy lines of advance—the identification of new clinical entities, the correlation of blood pictures with a number of diseases hitherto unstudied or imperfectly investigated hæmatologically, and the proof of the septic nature of many of the specific infections. There can be no doubt that hæmatology has been making rapid advances but the rate of progress can scarcely be appreciated unless in some such work as that at present before us we have an opportunity of realising the numerous changes necessitated within a very short time. For example, we find in this book that fresh space has had to be devoted to trypanosomiasis, kala-azar, spotted (Montana) fever, and cyanotic polycythæmia; that the blood changes of a considerable number of familiar conditions have required revision; while it is claimed that hæmatology has proved the bacteriæmic character of enteric fever, Malta fever, pneumonia, scarlet fever, and possibly rheumatic fever. The account of trypanosomiasis supplies a very satisfactory but brief history of this condition, with a clear description of the worm-like organism of which there is an admirable illustration. It is suggested that although the detection of trypanosomata in the blood affords the key to the diagnosis, yet when no organisms can be found a well-defined anæmia with a low leucocyte count, characterised by an excess of large lymphoid cells and by moderate basophilia, gives a very suggestive blood picture. The Leishman-Donovan bodies of kala-azar are figured, while it is remarked that the blood pictures of this disease and of Malta fever are very similar, apart from the parasitology of the blood. The account of the examination of the blood by clinical methods is extremely lucid and orderly and new instruments and new methods of work are described with such simplicity that the student should have no difficulty in mastering the technique. We are informed that in the preparation of this edition much new material has been gleaned from the consultation of more than 900 recent references to hæmatological literature and it is extremely satisfactory to note that a large number of these references indicate due appreciation of the labours of British investigators. From the care with which this volume has been revised it can be cordially recommended to all who wish to obtain information of recent advances in hæmatology and also to those commencing this important branch of study. For the beginner it may be well to remark that much of the spelling is American rather than English; although this entails no difficulty of comprehension it involves a certain amount of correction for the purpose of examination and does not appeal to British eyes.

---

[1] THE LANCET, March 3rd, 1900, p. 623.

LIBRARY TABLE.

Indian Toxicology. By F. N. WINDSOR, Captain, I.M.S., M.B. Cantab., M.R.C.S. Eng., Chemical Analyst and Bacteriologist to the Government of Burmah. London: W. Thacker and Co. 1906. Pp. 99. Price 3 rupees.—The scope of this little book is limited to the poisons which are used in India, by which means it is hoped that the contents may be of practical use to both medical men and students in that country. The author rather quaintly states that other poisons may be considered as "toxicological curiosities" for which larger text-books about European toxicology must be consulted, "although the information will prove of no use to them in their future career in India." It is equally certain that English readers will find within these pages reference to some few poisons which they are not likely to find mentioned in English text-books or to encounter in practical work. This little book only consists of six chapters and of these four deal with generalities, such as the scope of the science, the recognition of poisoning, the methods of analysis and examination, and the general treatment of poisoning. In the last two chapters there is a classification of poisons into corrosives and irritants and vegetable and animal poisons. It must be admitted that there is nothing peculiarly Indian in the group of corrosives and irritants unless we note the ease with which common poisons can be purchased in the bazaars and the relatively greater frequency of their employment for poisoning cattle. Another source of danger is due to the carelessness of native shopkeepers who keep drugs and foodstuffs in close proximity and to the stock-in-trade of the hakims being frequently tied in the corners of dirty rags with no apparent means of distinguishing one white powder from another. Of the vegetable poisons, opium, datura, and aconite appear to be those most commonly employed; others described are strychnine, the oleanders, Indian hemp, cocaine, and more briefly, as being less common, plumbago, madar, and jequirity. The main facts are usefully epitomised in each case, while greater space is devoted to directions connected with the analysis and the detection of the different poisons. We are glad to note that in several instances the author does not hesitate to give details of physiological tests when chemical tests may lead to unsatisfactory results. Within the limitations which the author has assigned to his book he has succeeded in compressing much useful information, and he supplies many interesting brief records of actual cases which indicate that accidental and intentional forms of poisoning occur with sufficient frequency to call for the restrictions of the sale of poisons which obtain in this country.

Technique de Microbiologie Tropicale. By Dr. F. NOC, Médecin Major des Troupes Coloniales, Détaché à l'Institut Pasteur de Lille. With a preface by Dr. A. CALMETTE. Illustrated. Paris: Octave Doin. 1905. Pp. 320. Price 4 francs.—This concise volume is more comprehensive than the title of the book would lead us to expect. The book is more than a laboratory guide, for it deals not only with technique, but also with the anatomy of, and to some extent the bionomics of, parasites concerned in the etiology of tropical ailments. The subject is arranged in four parts. The first part of the book is devoted to the equipment necessary for a laboratory in the tropics, to the preservation and methods of transmitting pathological specimens, and to the study of mosquitoes, ticks, and other propagators of infection. The second part of the book is concerned with "diagnostic microbiologique," of which the first chapter deals with a clinical study of the blood in persons living in warm climates. The second chapter deals with malaria parasites, piroplasmosis, trypanosomiasis, spirillosis, filariasis, and the serum diagnosis of Malta fever, dysentery, and typhoid fever. In Chapters III. and IV. intestinal and skin parasites are fully considered. In the third division of the book pestilential maladies, such as plague, cholera, and yellow fever, are studied. In the fourth and last section the prophylaxis of several of the more prevalent tropical diseases is discussed. Dr. Noc's book is admirable; it is well illustrated, well written, and presented in a manner which is at once easy to follow and thoroughly scientific.

Indigestion: the Diagnosis and Treatment of the Functional Derangements of the Stomach, with an Appendix on the Preparation of Food by Cooking, with especial reference to its use in the Treatment of Affections of the Stomach. By GEORGE HERSCHELL, M.D. Lond. Third edition, entirely rewritten. London: Henry J. Glaisher. 1905. Pp. 293. Price 5*s.* net.—Indigestion as a diagnosis is rarely justifiable, since, as Dr. Herschell himself writes, "it is a matter of common knowledge that the group of symptoms to which we apply the term for clinical convenience is common to many different affections of the stomach, and modern methods of examination have enabled us in the majority of cases to find out without difficulty the exact cause of the trouble." This quotation gives accurately the aims and scope of the work before us, and we may say that Dr. Herschell has been successful in his presentation of the methods of investigation and treatment of the common disorders of the digestive processes in the stomach and that his classification rests on a rational basis. In adopting the title of indigestion for his work he is perhaps less than just to himself, since he deals in a detailed manner with a variety of gastric disorders of which the varying symptom-complex implied by the term "indigestion" comprises but a part. There can be little doubt that in this country the methods of intragastric examination, by which so many advances in diagnosis and treatment have been made, have been greatly neglected and that in this respect we are much behind the American and continental practitioners. A useful chapter in Dr. Herschell's book is that indicating the cases for which such methods are unnecessary and those in which diagnosis without them cannot be rationally made. The style in which the book is written is somewhat popular and at times racily descriptive, while the scornful references to the "physicians of the nineteenth century" and to the "titled heads of the profession" are perhaps hardly in the best of taste.

The Mummy and Miss Nitocris: A Phantasy of the Fourth Dimension. By GEORGE GRIFFITH. London: T. Werner Laurie. 1906. Pp. 312. Price 6*s.*—Mr. George Griffith's scientific or quasi-scientific romances are always amusing and those who read his fantastic romance "A Honeymoon in Space" will not be disappointed with this his latest excursion into the world of transcendental geometry. Given a protagonist who has attained to the fourth dimension and all things are possible. Although we ourselves have never been able to form any clear mental picture of the fourth dimension, we have read Mr. Griffith's novel with interest and we can commend it to our readers as a book that is an agreeable relief from the study of problems which have to do with the physical affections of our poor bodies.

A Vocabulary of Malay Medical Terms. By P. N. GERRARD, M.D. Dub. Singapore: Kelly and Walsh, Limited. 1905. Pp. x.-107.—This little book should be found useful by the [illegible] men class for whom it has been compiled [illegible] and magistrates. The preface is particularly interesting and gives sundry native beliefs as to medical matters which should certainly be taken into consideration by any European medical man who wishes to treat a Malay patient. Besides the vocabulary the book contains specimen conversations with patients supposed to be affected with various diseases and Snellen's test-types in Arabic lettering with a colour-vision test. One correction we must point out to Dr. Gerrard, and that is that "Crawford's Vocabulary" should surely read "Crawfurd's Vocabulary."

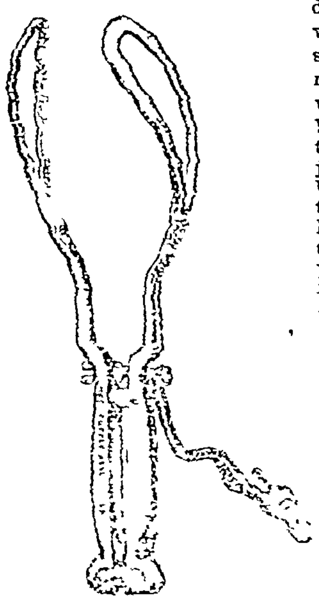
JOURNALS AND MAGAZINES.

Birmingham Medical Review (March).—In some remarks on Cases of Intestinal Resection Mr. Albert Lucas speaks favourably of end-to-end anastomosis by means of Murphy's button as more likely to leave a free opening than is lateral anastomosis with sutures. Dr. W. H. Wynn writes in commendation of Dr. F. J. Poynton's suggestion to employ citrate of sodium as a means of preventing too firm coagulation of cow's milk when used for feeding infants, and notes that in certain cases a similar procedure might be useful also for adults who are on a milk diet. The concluding portion of a useful abstract of recent work on Opsonins and Vaccine Inoculations, written by Dr. J. G. Emanuel, appears in this number.

New Inventions.

IMPROVED MIDWIFERY FORCEPS.

As it seems desirable for several reasons to avoid the necessity of introducing the left lower blade first I have devised a pattern of midwifery forceps which seems to meet the requirement. In these forceps it will be noticed that the blades do not cross, that the lock is not at the junction of the handle and blade but at the end of the handles, and that the lock can be fixed by a single turn of a stud. To prevent the blades from rolling one on the other a guide peg on the lower blade fits into a slot on the upper. A small swivel screw, attached at the junction of the blades and handles, prevents the handles from flying apart, a traction rod can be used if necessary, as in the illustration. I have used this pattern of forceps in a great number of cases and others, as well as myself, have been surprised at the ease of application.



The forceps were made for me by the Medical Supply Association, of Gray's Inn-road, London, W.C.

Ladbroke-grove, W. H. B. TAYLOR MORGAN, M.D. Edin.

ASYLUM REPORTS.

Derby Borough Asylum (Sixteenth Annual Report for the Year 1904).—The daily average number resident in this asylum during 1904, the last year reported upon, was 321. The admissions numbered 88, the discharges 48, of which 34 were recovered (giving a recovery-rate of 43·6 per cent. of the admissions), and the deaths 32, or 10 per cent. of the daily average resident. The recovery-rate is a satisfactory one: the death-rate is about the average for county and borough asylums. Amongst the numbers resident were 17 private patients and 15 boarders from a county asylum. For the past five years the average annual admission-rate for Derby patients has been 80. The character of the admissions is reported by Dr. S. Rutherford Macphail, the medical superintendent, to have been unfavourable, many of the cases being imbecile, epileptic, or sufferers from incurable dementia. In only 43 of the 88 admissions could recovery be reasonably expected. About two-thirds of the admissions suffered from recognisable physical disease, and this is stated to be the usual proportion. In respect to causation, hereditary predisposition to insanity or other nervous disorders was present in 36 per cent. of the admissions. In several of these cases the hereditary taint was denied by the relatives notwithstanding the fact that members of the family had been in the asylum. Dr. Macphail thinks it safe to assume that 50 per cent. would more correctly represent the amount of hereditary predisposition. Alcoholic excess was ascertained in 20 per cent., and in a like number the predisposing influence of various bodily disorders was established; these are not individually referred to. The statistics of 16 years have been collected in respect to relapse of patients *discharged recovered*; out of 521 patients so discharged, 105, or 20 per cent., were readmitted; not an undue proportion, as Dr. Macphail observes. It is found that patients take a longer time to recover than was the case ten years ago; the average period of residence has increased of recent years. Showing the importance of the early treatment of insanity, as of other diseases, it is to be noted that in the 34 patients discharged recovered the disorder had existed in 32 for less than three months at the date of admission. Out of 32 deaths only three were due to tuberculosis, and since the opening of the asylum the percentage of deaths from this cause upon the total number of deaths is 9·3, which is but little more than one-half the percentage for public asylums as a whole. There were 11 vacant beds in the asylum at the date of the committee's report, but these were all in the private department. Under the auspices of the Brabazon Employment Society the institution is visited by ladies who instruct the patients in various forms of light employment and still further manifest their interest by visiting at their homes those who have recovered. From the report of the Commissioners in Lunacy it appears that a detached block for 30 female private patients has been provided. From this report we gather that the asylum is maintained in excellent order.

St. Andrew's Hospital for Mental Diseases, Northampton (Report for 1905).—The average number daily resident in this institution during the year was, according to the report of the medical superintendent, Mr. J. Bayley, 410. 78 patients were admitted, of whom 66 were first admissions. The discharges numbered 95, of whom 46 were discharged recovered, which gives the very high proportion of 74·19 per cent. on the admissions, excluding transfers from other asylums. This figure is above what might be expected even from an institution such as this, which no doubt receives a large proportion of cases favourable for treatment. The statistical tables appear to give the percentage of recoveries on the total admissions (including transfers) and therefore a comparison of the above-mentioned figures with similar ones in previous years is not possible. Of the 46 patients discharged recovered 27 were under treatment for from three to nine months. The percentage of deaths on the average number resident was the low one of 6·34. As regards causation of insanity, trouble and worry were responsible for 24 per cent. of the admissions, alcoholic excess for between 11 and 12 per cent., whilst hereditary influences were ascertained in no more than 8 per cent., an extraordinarily low proportion, probably largely explained by the difficulty of eliciting information on the subject of heredity from persons of the social class to which those with whom this institution deals largely belong. In no less than 70 of the 78 admissions the mental disorder assumed the form of mania or melancholia; according to the statistical tables not a single case of delusional insanity was admitted. The hospital has the advantage of a separate residence, situated in North Wales, to which patients are sent for change, which is no doubt excellent alike from the point of view of the patients and the nursing staff. St. Andrew's Hospital is an institution for the middle and upper classes, a large proportion of the patients being received at very moderate rates of payment. The reports of the Commissioners in Lunacy, who visit this and similar institutions twice yearly, are appended and are of a nature satisfactory to the management.

THE LANCET.

LONDON: SATURDAY, MAY 12, 1906.

Sanitary Administration in the Port of London.

THE reports of the medical officer of health of the Port of London testify year by year to the importance and variety of the services which the corporation of the City, in its capacity of sanitary authority for this great seaport, renders to the metropolis and to the country as a whole. The most recent of these reports, that for 1905, is no exception to the rule. One of the most important duties undertaken by the medical staff is in relation to infectious diseases on shipboard. Of these, as many as 211 cases came under notice during the year, including 65 cases of enteric fever, 24 of small-pox, six of cholera or suspected cholera, and nine of suspected bubonic plague. In connexion with the last disease arrangements which had been made for the destruction of rats on board vessels and in warehouses within the docks resulted in over 50,000 rats being caught and destroyed during the year. As regards cholera, special vigilance was called for in the autumn in consequence of prevalence of this disease in Russia and its extension along the River Vistula into Germany. At the suggestion of the Local Government Board all persons arriving in the Thames from ports on Russian and German littorals were medically examined and the destination of passengers or immigrants was in all cases investigated in order to permit notification to the sanitary authorities of the places to which they were bound. Addresses given in these circumstances have often proved to be inaccurate in the past and it is satisfactory to read that in consequence of special arrangements made last year the persons who could not be traced after leaving the vessels formed a comparatively small proportion of the whole. On the question of alien immigration Dr. H. WILLIAMS reproduces a table from the report of the Commissioner-General of Immigration of the United States in illustration of the care taken at American ports to exclude immigrants who are found to be physically or mentally deteriorated or who suffer from disease which would prevent them from becoming useful citizens. Next year it may be possible to chronicle some action in the same direction, however small, at British ports. As we pointed out in an article in THE LANCET of Feb. 2nd last, describing the arrangements made in the Port of London for carrying into effect the provisions of the new Aliens Act, this legislation from the point of view of the public health of the country is on right lines and gives promise of good results if reasonably administered. It is to be hoped that this consideration may be kept in mind in the political warfare which has arisen over the operation of this Act. It is certainly difficult to consider many of these aliens as desirable additions to our population after reading the description given by Dr. WILLIAMS of the filthy conditions which are encountered on some of the vessels in which they arrive.

The work of inspecting foodstuffs within the area of jurisdiction of the port sanitary authority has come to be of considerable magnitude. The port authorities have the advantage of being able to inspect foods in bulk and to condemn articles which are unfit for food before they have become scattered throughout London and the provinces. During the year it was necessary to condemn over 15,000 carcasses of mutton or lamb, 3517 quarters of beef, and 437 cases of veal, pork, and butchers' offal. In course of examination of tinned foods 1121 tins of preserved meat, 5404 of preserved fish, 5488 of fruit, and 104 of condensed milk were condemned. Other articles seized comprised 524 crates of frozen rabbits and some 100,000 eggs. Dr. WILLIAMS relates an interesting sequel to the sinking of the French steamer *Curavellas* below Gravesend with a large cargo of coffee on board. When this coffee was recovered it was necessary to regard a portion of it as unsound on account of mouldiness and fermentation. It was decided by the Customs authorities that this damaged coffee might be "denatured" by being mixed with an adequate portion of slaked lime. Some 500 tons were treated in this way and the mixture was disposed of "for manurial purposes." It afterwards became apparent, however, that the persons interesting themselves in this mixture of lime and coffee were incurring expenses which seemed out of proportion to the value of the material as manure. Observations were made and the subsequent history was that the whole was shipped to Antwerp where there was reason to believe that the material was washed to remove the lime, dried, and afterwards roasted and probably used for the purpose of "bulking" with other coffee.

One of the most important sections in the report relates to the condition of quarters occupied by the crews of merchant vessels. The position of port sanitary authorities in this matter is by no means satisfactory. Something may be done, and is done, to secure mitigation of "nuisances" and to obtain cleanliness of crews' quarters. But the port medical officer of health is practically powerless to deal with gross sanitary defects which result from faulty construction and neglect of elementary principles of lighting and ventilation. In the ordinary merchant steamer the space allotted to the crew, and used both for sleeping and for messing, is thrust as far forward as possible. The space in question is divided longitudinally in order to secure the customary, and probably necessary, separation between firemen and seamen. A minimum floor area of 12 square feet per head is prescribed by Board of Trade regulations but this in practice secures a wholly inadequate air space, while ventilation is frequently almost non-existent. Port holes in the bows in ordinary circumstances have to be kept closed. Ventilators are frequently so arranged that they open immediately over the bunks. A strong down draught falls on the occupants, with the result that these ventilators nearly always are blocked up at the first opportunity. In these circumstances, especially in rough weather and when the fore cabins are full of wet clothing, the condition of the crew's quarters is often unwholesome in the extreme. The matter has again and again been brought to the notice of the Board of Trade but with little or no result. It might be supposed, however, that care would at least be taken to see that the present regulations regarding space, ventilation, and lighting, inadequate though they are, receive recognition in the construction of new vessels. Some observations made by Dr. WILLIAMS regarding a steamer built as lately as 1900 seem to show that this is not always the case. The inspector's visit was made in the Upper Pool in broad daylight. Going to the crew's quarters he found that all the available lamps, four in number, had been lighted in order to provide sufficient light for the crew to see by. The only way in which daylight could be admitted into the quarters on either side was by two seven-inch glazed ports, and as usual the bunks occupied the same side of the quarters as the glazed ports and greatly obstructed what little light could be admitted by this means. To representations by the port sanitary authority the owners returned the usual answer that the quarters "had been built to the requirements of the Board of Trade and duly passed by them." Representations then made to the Board of Trade that such inadequate lighting transgressed official regulations elicited the reply that at Cardiff, where the vessel had gone, the Board of Trade inspector considered that no breach of official regulations existed. Dr. WILLIAMS will receive the support of all who have practical experience of the subject when he urges that the Board of Trade should take powers to improve the conditions of life of the seamen in the following directions: (*a*) crews' quarters should not be placed in the fore part of the ship; (*b*) improved and efficient ventilation, lighting, and heating; (*c*) increase of cubic space; and (*d*) separate messroom and washhouse. Dr. WILLIAMS points out that if crews were berthed aft all these requirements could be carried out with the greatest facility. This is a matter to which the attention of Parliament should be directed in connexion with the Government's Merchant Shipping Bill. One clause in this Bill confers powers on the Board of Trade to appoint committees of experts on any questions relating to the working of the Merchant Shipping Acts. It is to be hoped that the Board of Trade will take an early opportunity of utilising these new powers to obtain advice and guidance on elementary sanitary principles which at present appear to receive too little recognition in official regulations regarding the construction of vessels and too little consideration in the everyday practice of the Board's officers.

The Feeding of Children attending Public Elementary Schools.

ON March 2nd the Education (Provision of Meals) Bill passed its second reading in the House of Commons and was referred to a Select Committee. In our issue of March 10th we commented upon the provisions of the Bill and pointed out that the local authorities, in whose hands the organisation for the providing of food for the children is left, would have no easy task. Two points have especially to be considered: firstly, the selection of recipients of meals, and secondly, the organisation for the distribution of such meals as it may be determined to give. The Select Committee which is now sitting to consider the provisions of the Bill will have its [illegible] considerably lightened by the information contained in a White paper, Cd 2926, which has recently been presented to Parliament by command of His Majesty and which contains information collected by the Board of Education and the Foreign Office regarding methods adopted in great continental and American cities for dealing with under-fed children. The Foreign Office began to collect this information at the request of the Board of Education in March, 1905, and the return is dated April 11th, 1906. A schedule of questions was drawn up covering all the points which seemed likely to arise in a discussion of the subject, the most important being the following:—What meals are provided (i.e., breakfast, dinner)? Are meals given to all children attending elementary schools? If not, how are those to be fed chosen? Are any steps taken to recover the cost from parents who can afford to feed their children but do not? Another question was a request for information covering the last three years as to (*a*) the school population, (*b*) the number of meals given, (*c*) contributions from public funds: (i.) imperial, (ii.) local; (*d*) voluntary contributions, (*e*) payments by parents, and (*f*) total cost. The countries included in the return were Austria and Hungary, Belgium, Denmark, France, Germany (including Würtemberg and Luxemburg), Holland, Italy, Norway, Sweden, Spain, and Switzerland, and of cities in the United States, New York, Philadelphia, and Chicago.

The lessons to be learned from the replies form an interesting document. In all the countries mentioned some attempt is made to provide food or other form of assistance for children presumably in need thereof. Stated broadly, in only very few instances were any funds received from the State towards the expense of feeding children, but in nearly all cases assistance was received from the local funds. If therefore we in this country determine to feed our children upon the same lines as have been adopted by certain of our neighbours it seems pretty sure that the money for the purpose will be an additional charge upon the already overburdened ratepayer, and equally sure that such a proposal will meet with considerable opposition on both sides of the House. It is interesting to note that in giving evidence before the Select Committee upon April 26th Mr. JOHN SCOTT, headmaster of the Wood Close School, Bethnal Green, a man of 23 years' experience as a teacher, said that in his view the under-feeding question was, on the whole, "quite trivial, the question of clothing and boots was much more important." From their very birth the children of our poor are fed in too many instances wrongly, even where the wages of the breadwinner are good and where a proper proportion of those wages is devoted to the sustenance of the family. This has been strongly commented upon by medical men and by all whose charitable work brings them into close relations with the poor, and statisticians have employed the fact in explanation of the figures of mortality, but the similar ignorance that is prevalent with regard to the clothing of the young, perhaps because it leads to less obvious and immediate consequences, has somewhat escaped attention. This point must be noted as forming an obvious argument for the regular inspection of school children by a medical officer, since popular ideas of what constitute sufficient and suitable food and clothing for children seem to be confused to the same degree.

Ideals are all very well in theory but they have to give way to hard facts. In a properly organised society all children would be fed by their parents with as much regularity as are young animals or birds, or as children are to this day in primitive communities. But the conditions of modern life in what are called—some would say ironically called—civilised communities have led to the breaking up of the home, to the loosening of the bonds of parental responsibility and to children being "dragged up" anyhow, instead of being brought up by a careful parent. It is for the medical profession, so far as possible, to help modern society in the awkward fix in which many complex conditions have placed it. The reformation of the home is the most obvious remedy, but it is far easier to name a remedy than to find it. The schemes included in the return are but makeshifts, but at present they seem to be the best which can be made use of and if the Select Committee will carefully consider the information it may be able to provide a really useful measure. The country will have to pay a bill in some way to meet any charges found necessary and it is well that this should be recognised even before the machinery to meet the charges is proposed. The education of our children no less than their physique is bound up in the larger affairs of their environment and the schoolmaster, the physician, and the sanitarian should work together to arouse a public sense of the vast national importance of the whole question. Carefully tabulated medical statistics would assist our legislators to logical conclusions and practical action. "The children want bread and the suggested remedy is figures," we hear many kind-hearted people say; but it must be remembered that as yet no two people are agreed as to how many children want bread, much less to what extent the nation is thereby weakened in its effective population. Such a method of universal and systematic inspection of school children as is advocated by the National League for Physical Education and Improvement would supply at this junction information that would be simply invaluable to our legislators.

◆

The Outbreak of Yellow Fever in British Honduras in 1905.[1]

Professor Rubert W. Boyce visited British Honduras in the autumn of 1905 whilst yellow fever was prevalent and we are now favoured with a report of his observations and a statement of his plans for prevention of the disease. From so astute an observer we expect a masterly report and in this expectation we are not disappointed, for Professor Boyce's publication is succinct in its statements, wonderfully complete, and written in a manner at once clear and convincing. Starting with the definite knowledge that yellow fever is conveyed by the stegomyia fasciata mosquito, a fact proved conclusively in 1900 by Reed, Carroll, Lazear, and Agramonte, Professor Boyce proceeds to show the distribution of stegomyia, its constant presence in all districts in which yellow fever prevails, and the sanitary conditions which obtain and serve as factors in favouring the continuance of this species of mosquito. That the town of Belize is infested by the stegomyia is not to be wondered at when the habits of this mosquito and the sanitary conditions in Belize are considered. The stegomyia fasciata is essentially a "domestic" mosquito; its larvæ are found in the receptacles used for the storage of water near houses and in the rain water collecting in tins, bottles, or crockery thrown out from the houses and allowed to lie about the gardens, yards, or outhouses, where it flourishes to the exclusion of other mosquitoes. Rain water stored in barrels is the commonest form of water-supply both for washing and also to a large extent for drinking purposes in the town of Belize and as these barrels have no lids they are a favourite and constant habitat of the larvæ of stegomyia. Water is also stored in vats and tanks; of wells there is a fair number but as almost all these are unprotected they constitute, in addition to the barrels, breeding places for this mosquito. It is plain, therefore, that if yellow fever is to be fought in Belize a controlled and protected water-supply is necessary; all vats, tanks, and barrels must be screened permanently with wire gauze or temporarily with cheese cloth. The eradication of malaria, to which Belize is also liable, can also be effected but, of course, on different lines. The most prevalent anopheles mosquito which transmits malaria in Belize is the Cellia albipes, although another undetermined species is also present. This mosquito is absent from the water receptacles near houses but is met with in the marsh land around the town, in the mangrove swamps, in the shallow weed-grown gutters of the streets, in shallow pools, in waste places, and in the cattle ponds. To free Belize from yellow fever and malaria would seem, therefore, a simple problem, for the areas of distribution of stegomyia and anopheles are patent and their eradication is only a matter of destroying their breeding grounds in and around the town.

The early recognition of yellow fever and the early notification of the disease are points upon which Professor Boyce lays great stress. In British Honduras the stegomyia fasciata can live all the year round owing to the country being within the zone of the permanent distribution of this mosquito; there is therefore no season during which yellow fever may not prevail. Sporadic cases of the disease are liable to occur at any time, the only element required in addition to the stegomyia to produce an outbreak being a person or persons suffering from yellow fever. As the disease may be introduced at any season of the year from some one of the neighbouring countries, it behoves the medical authorities to be constantly on the alert. The clinical symptoms being the only readily available means of diagnosis, seeing that no parasite is demonstrable in yellow fever, as in the case of malaria, filaria, and other ailments, it is not always possible to come to an early diagnosis as to the nature of the illness, and in many cases of malaria and influenza the clinical signs and symptoms closely resemble those present in yellow fever. Fortunately, the post-mortem signs of yellow fever are characteristic and require no microscopical confirmation, and Professor Boyce very rightly draws attention to the importance and imperative necessity of obtaining a post-mortem examination in the first suspicious deaths. In this way alone can the medical practitioner feel justified in declaring in the early outbreak of the disease that it is really yellow fever he is dealing with and thereupon notifying the disease to the authorities. Early notification of any epidemic disease, indistinguishable by characteristic features apart from clinical signs and symptoms, is at all times a difficult and delicate matter, and medical men hesitate to take so serious a step without conclusive evidence. Hesitation to notify may involve a given community in the throes of an epidemic; whilst, on the other hand, the medical officer who reports the presence of the disease and subsequently finds that he is mistaken has involved the community in needless expense by upsetting commerce. The careful medical officer, however, will tell his difficulties to those in authority and proceed to isolate a suspicious case without necessarily raising an alarm. On board many ships, in the area infested by the stegomyia, mosquitoes are found and it only requires that a person should develop yellow fever on board to find the disease attacking other members of the crew or passengers, or it may be communicated, when the ship reaches harbour, to dock hands, Custom House officials, and others whose duty is to go on board the vessel or to handle the cargo. The need of careful medical inspection, of properly organised quarantine, and of means of freeing from mosquitoes the ships leaving ports infected by yellow fever is evident. Professor Boyce deals with these subjects and brings forward a number of practical suggestions whereby the danger may be eliminated.

---

[1] Report to the Government of British Honduras upon the Outbreak of Yellow Fever in that Colony in 1905; together with an account of the Distribution of the Stegomyia Fasciata in Belize and the Measures necessary to stamp out or prevent the Recurrence of Yellow Fever. By Rubert W. Boyce, M.B., F.R.S. Messrs. J. and A. Churchill, 7, Great Marlborough-street, London, W. Pp. 104. Illustrated. Price 3s. 6d. net.

A recently published paper by Dr. F. I. Wilbur on the Home of Yellow Fever states that the stegomyia fasciata is not a native of American seaports in the Mexican Gulf, although it is found there, and endeavours to trace the migrations of this mosquito. Dr. Wilbur's opinion is that the Sargasso Sea is the real home of the stegomyia fasciata and of yellow fever; that in the still water of this sea of seaweed, around which the ocean currents sweep like rivers, is to be found the home of the disease. The seaweed is the *Sargassum bacciferum* and it covers an area of the sea nearly equal to that of Europe. Ships on their way to the seaports of the Gulf of Mexico and to the northern ports of South America frequently traverse this continent of seaweed and there become infected. Dr. Wilbur draws attention to the fact that yellow fever was unknown in America before the time of Columbus and it is significant that the route of his journey is known to have been across the Sargasso Sea. This conception of the area of infection is interesting and may or may not be correct, but it shows the trend of thought at the present day in regard to the origin and etiology of disease.

Annotations.

"Ne quid nimis."

BARON TAKAKI'S LECTURES.

Baron Takaki, the late Director-General of the Medical Department of the Imperial Japanese navy, has delivered two of the three lectures on the Preservation of Health amongst the *Personnel* of the Japanese Navy and Army. The lectures were given in the Governors' Hall of St. Thomas's Hospital and Baron Takaki seemed greatly pleased at the enthusiastic reception accorded to him by the audience that thronged the spacious hall. By the aid of coloured charts excellently lighted from the floor of the hall by means of powerful electric illumination the lecturer was able to interest those present in following the course of his remarks on the statistics of the Japanese navy bearing upon the prevalence of beri-beri and the eradication of that disease by the establishment of a proper diet, instituted by Baron Takaki in spite of great opposition. A full account of these lectures will appear in our columns.

THE ALLEGED INCREASE OF INSANITY.

The recent urgent appeal of a *Times* correspondent for a well-organised application of the resources of medical science to the investigation of insanity as a physical disease deserves serious attention. It is doubtful, however, whether the appeal was strengthened by the unqualified assertion that the alleged increase of insanity is a simple and an established fact. Such an assertion naturally suggests the inquiry as to the ground on which it is based. It is an undoubted fact that the number of the insane in England and Wales under the control of the Commissioners in Lunacy has steadily and even rapidly increased during the past 60 years; indeed, the *Times* correspondent points out that the number, which did not exceed 21,788 in 1844, had increased to 119,829 on Jan. 1st, 1905, and he remarks that "the effect of the mere sweeping up and incarceration of the harmless so-called 'naturals' of country villages was exhausted within a very few years of the passing of the Lunacy Acts of 1845." How do facts square with this assertion? At the census in 1871 householders were for the first time required to state whether any member of their family was lunatic, idiot, or imbecile, and it can hardly be conceived that the numbers so returned would err on the side of over-statement. The census number of the insane in 1871 exceeded, however, by 12,284 the number known to, and reported upon, by the Commissioners in Lunacy in that year. Similar census information was required and collected in 1881 and 1891, and this reserve of cases, unknown to the Commissioners but included in the census returns, fell successively to 11,390 and 10,586, which hardly supports the assertion that all the insane had been "swept up and incarcerated" within a very few years of the passing of the Lunacy Acts of 1845. At the last census in 1901 the substitution in the householders' schedule of the term "feeble-minded" for "idiot" probably induced a fuller and more accurate return of persons of unsound mind in the English population, with the result that the number of the insane in the census returns for that year exceeded by 24,710, or 23 per cent., the number under the control of the Commissioners in Lunacy on Jan. 1st, 1901. These facts, although they afford no basis for deciding whether insanity is really increasing, prove that no trustworthy conclusion can be drawn from the increasing numbers of the insane brought from time to time within the cognisance and control of the Commissioners in Lunacy. It should, however, be pointed out that while the census numbers returned under similar conditions in 1871, 1881, and 1891 showed an increase in each of the two decades, the rate of increase, which was 7·04 per cent. in 1871-81, fell to 3·23 per cent. in 1881-91. Unfortunately, the substitution of "feeble-minded" for "idiot" at the census in 1901 destroyed the value, for comparative purposes, of the numbers of insane then enumerated, although it may more accurately represent the true number of persons of unsound mind. It is impossible, therefore, to use the census figures in 1901 for testing the reality of the alleged increase of insanity between 1891 and 1901. There are absolutely no satisfactory statistics for solving the most important problem whether the probable increase in the ratio to population of existing cases of insanity really implies an actual increase of occurring cases of insanity. We know, however, that in recent years there has been a marked decline both in the death-rate and recovery-rate among the insane residing in asylums; and further, that the mean age of the residents in asylums is constantly increasing. This obviously implies accumulation of cases, which when duly allowed for shows that the number of new cases required in recent decades to account for the increase of numbers under the control of the Commissioners is a decreasing number. In their last report the Commissioners, moreover, call marked attention to the recent disproportionate increase in the number of aged persons suffering from senile dementia transferred from workhouses to asylums and further point out that the proportion to population of all lunatics aged upwards of 65 years admitted to asylums has steadily increased from 9·9 in 1884–88 to 14·3 in 1899–1903. These facts throw much doubt upon the alleged increase of lunacy and they prove that no sound conclusions on the subject can be based upon the increasing numbers of existing cases under the control of the Commissioners in Lunacy.

MULTIPLE POLYPI OF THE GASTRO-INTESTINAL TRACT CAUSING REPEATED INTUSSUSCEPTION.

IN the *Intercolonial Medical Journal of Australasia* Dr. D. M. Officer has reported the following remarkable case. A boy, aged nine years, was admitted to hospital on Oct. 21st, 1904. He had been ill for 12 months with abdominal pain and vomiting which occurred in attacks of from a few hours to a day's duration. At first the attacks occurred once a week or once a fortnight but for the previous month they had occurred every day, lasting a couple of hours with short intervals of relief to be followed by other attacks. The bowels had always acted regularly but latterly the motions were slimy and on administering a purgative prolapse of the rectum followed. The pain was so severe that the boy cried and writhed. It was referred to the umbilical region but tended to shoot towards the shoulder. Food did not induce attacks but when solid it tended to make the pain more severe. On examination a swelling was seen below, and to the left of, the umbilicus. It was freely moveable and felt semi-solid. Nothing was felt per rectum. After admission there were several attacks of pain in the upper abdomen in which the patient perspired freely and became very pale and cold. In the more severe attacks a large swelling appeared in the left subcostal region. This rapidly increased in size and then diminished either spontaneously or after the administration of morphine. Exploratory laparotomy was performed but nothing abnormal was found. Moveable kidney with intermittent hydronephrosis was diagnosed. After the wound healed the left kidney was explored and was found to be freely moveable. Nephrorrhaphy was performed. On Feb. 4th, 1905, the boy was readmitted with a history of further attacks. After admission there were several attacks in which a tumour appeared and subsided with the pain. Once three distinct tumours were present together. After administering an enema they subsided and the pain ceased. On Jan. 14th, 1906, he was again admitted with the same history. An attack had commenced on the previous day and persisted. A large ill-defined tumour was found on the left side. An enema failed to relieve the symptoms but a large quantity of blood came away. Laparotomy was performed and an intussusception involving about four feet of the small intestine was reduced. During the reduction some lumps were felt, but the patient was almost moribund and further exploration was therefore impossible. He never rallied and died an hour after operation. At the necropsy the whole gastro-intestinal tract excepting the ileum was found to contain adenomata, some of which were sessile and others pediculated. They numbered 41 and the largest was in the stomach. Cases of multiple polypi of the intestines are rare and few cases in which they were so numerous as in the case related above have been recorded.

THE ACTION OF SILVER FLASKS ON BRANDY.

A CORRESPONDENT submitted to us recently some brandy which had been left for some time in a silver flask. The flask had the silver hall-mark upon it. The brandy had darkened considerably in colour and contained a dark brown flocculent sediment which on analysis proved to be copper combined with tannin. There was also a very distinct amount of copper in solution in the brandy, apparently in the form of acetate. These results suggested a few experiments which ultimately proved that genuine old brandy dissolves in a quite short time a very distinct amount of copper, the copper so dissolved ultimately combining with the tannin to form a tannate of copper. When a few shillings were placed in some old brandy and the spirit was examined after a day or so a distinct amount of copper was found in it. On adding a penny to the shillings in this experiment the dissolving effect was considerably increased, due, no doubt, to the stimulus set up by galvanic action. Spurious brandy, oddly enough, did not appear to dissolve any appreciable amount of copper from a silver coin, so it may be concluded that the action of old brandy is partly due to the acetic acid which it invariably contains, plain spirit being comparatively free from this acid. This view is supported by the fact that genuine Jamaica rum, which contains more acetic acid than does brandy, has a strong action on a silver coin, extracting very decided amounts of copper from it. Standard silver contains 7·5 per cent. of copper and evidently this alloy is readily acted upon by old brandy; it would seem desirable therefore to abandon silver unless it is absolutely unalloyed as a material for the brandy flask. Rightly or wrongly, it is the custom of many people to carry a brandy flask with them as a kind of sheet anchor in the event of faintness overtaking them or as an anodyne for colicky pains or other manifestation of digestive trouble. In the latter case the presence of copper in the brandy might easily aggravate the trouble as salts of copper frequently act after the manner of a powerful irritant poison, causing pain in the stomach and spasms. The simple precaution easily suggests itself that brandy should not be kept in a metal container but in glass.

THE NATIONAL ASSOCIATION FOR SUPPLYING FEMALE MEDICAL AID TO THE WOMEN OF INDIA.

THE report of this association for the year 1905 shows the very remarkable progress which has been made during the last seven years. There are now 12 provincial branches working under the central committee and there are some 140 local associations or committees attached to it. For the provision of medical aid to the women of India there are now some 260 hospitals, wards, and dispensaries officered by women and most of them directly governed by, or affiliated to, the association. This number compares very favourably with the 185 which existed in 1898. The total value of the various institutions engaged in furthering the work of the association amounts to the large sum of 3,83,37,000 rupees. During the year 1905 medical aid was furnished to 1,956,831 women and children, an increase in the numbers of some 472,000 over the year 1898. 44 lady doctors, 87 assistant surgeons, 274 hospital assistants, and a large number of midwives and nurses are employed in the various zenana hospitals and institutions. These figures show a marked increase over those for the year 1898.

A corresponding increase is evident in the disbursements and investments of the association. This period of seven years comprises the term during which Lady Curzon controlled the work of the association and it is not surprising, therefore, that the committee should wish to express its sense of the heavy loss which it has sustained by her departure from India and its appreciation of the very admirable work that she did for the association during her term as president. In her last address to the committee Lady Curzon said: "Some fears had been expressed that by the plan of bringing trained nurses from England for work in India under a scheme which had been put forward by her the work being done by nurses in India already might be interfered with. The scheme, however, for providing English nurses in every province was in no way intended to interfere with or check work already being done or capable of being done by other agencies." The need of properly trained English nurses in India is a very marked one and there can be no doubt that there is ample room for all the women who can be persuaded to undertake such work, whether they be trained at home or in India. We have already discussed this matter[1] and we can only congratulate the committee of this association on the good work, which it has done and hope that future years may witness as great an increase both in the prosperity of the fund and in the relief afforded to the suffering women and children of India as has attended its labours in the past.

THE TREATMENT OF PUERPERAL FEVER.

THE Midwives Supervising Committee has presented a most interesting report on the working of the Midwives Act, 1902, in Manchester, to the city council. The report is a long one and contains statements from the medical officer of health and the medical executive officer appointed to work under the medical officer of health in connexion with the supervision and training of the midwives in the city. There is included also a report from Dr. A. Knyvett Gordon, medical superintendent of the Monsall Fever Hospital, in reference to the treatment of the cases of puerperal fever admitted into that hospital during 1905 In this he gives most interesting details of the procedure adopted in the treatment of these cases. On the admission of the patient after a brief preliminary examination to eliminate any infectious disease which might call for her complete isolation, a further examination is carried out in the operating theatre under an anæsthetic, the patient having been prepared for any operative procedure which may be considered necessary. A swab is taken from the interior of the uterus and a complete study of the organisms found is subsequently made in the bacteriological laboratory. In all but five of the cases treated during the year 1905 the interior of the uterus was then curetted with a large sharp curette and the raw surface made was disinfected with undiluted izal fluid. The object of this operation is not only to remove any retained products of conception but also to disinfect thoroughly the interior of the uterus. In the further treatment an attempt is made to neutralise the poisonous products of the infecting organisms, and for this purpose large doses of bactericidal sera are employed. Two types of these sera have been used, one prepared from pure cultures of various streptococci isolated from cases of puerperal fever and the other prepared from pure cultures of the bacillus coli, also prepared from cases of puerperal fever. During 1905 the antistreptococcic sera were employed in 26 of the cases and the colon bacillus serum in four. In all cases large doses of the sera were employed, varying from 40 to 100 cubic centimetres; in no cases have any untoward symptoms developed, although occasionally the treatment seems to have been of no avail. All the cases admitted during the year, 41 in number, were very seriously ill, and all presented evidence of severe septic infection. 60 per cent. of the cases were attended by midwives, while in almost every case there appeared to have been unnecessary delay on the part of the midwife in sending for a medical man. Dr. Gordon asks the interesting question, Is it possible to determine whether the infection took place at the time of delivery or subsequently? He thinks it improbable that the incubation period is more than 48 hours in the case of the streptococcus or the bacillus coli, judging by analogy from other forms of wound infection. In his series of cases, however, this interval has been four days or longer in 20, or 57 per cent. In the cases attended by medical men the average interval has been three days and in no case has it been more than four days; in the cases attended by midwives, on the other hand, the average period has been four days and one of six or seven days has been by no means uncommon. The interval elapsing between the onset of septic symptoms and the notification of the case was in most of the cases unduly long and this is very unfortunate from the point of view of successful treatment. Dr. Gordon pleads for the admission of all cases of puerperal infection both of the mild and of the severe type into hospital, and in this we feel sure he is correct. These are essentially cases for hospital treatment but there is often considerable difficulty in getting them admitted into a hospital. Many general hospitals will not take them and there is no provision in London for their admission into the fever hospitals of the Metropolitan Asylums Board. We can only hope the time may come when their earlier notification will improve the chances of successful treatment, and that medical officers of health will be empowered in the future to insist upon their removal to a fever hospital as infectious cases when their home surroundings are considered unsuitable for successful treatment. The example of Manchester in this respect is one that might well be copied by other cities.

THE MEDICAL SOCIETY OF LONDON AND THE AMALGAMATION OF SOCIETIES.

A SPECIAL general meeting of the Fellows of the Medical Society of London was convened on May 7th to consider the following proposal by the council of the society:—

> That whilst asserting the desirability of an amalgamation of the various medical societies of London into a Royal Society of Medicine, the Medical Society of London can only agree to join in this effort provided: first, that the financial position of the new body is found to be satisfactory after the financial accounts of the various societies have been thoroughly investigated, and, second, that the privileges of the Fellows of the Medical Society are carefully safeguarded."

The question of the amalgamation of the London societies, details of which have from time to time been given in our columns, has reached a somewhat critical stage. The action of the Medical Society of London in the matter has been looked forward to with some interest, for it appears to some to be doubtful if a satisfactory financial basis can be arranged without its aid. The above proposal was very fully discussed last Monday, and not without a considerable degree of criticism. It was pointed out by several of the speakers that in return for the large contribution of books and money which would have to be made by the Medical Society, although some of the rights and privileges of the Fellows would be safeguarded, there were others which would not, such, for instance, as the case of general practitioners and country Fellows. However, some of the Fellows urged that in the interests of medical science and for the general good a further attempt should be made to clear up the difficulties of the position. In the end the proposition of the council was carried by 44 to 11 votes, a comparatively narrow majority over the three-fourths of the Fellows present necessary to carry a resolution of this special character. Had the proposition not been carried no further action by the Medical Society in the amalgamation would have taken place. As matters now stand, the Medical Society has expressed its approval of the principle of amalgamation provided the necessary financial investigations and arrangements can be made and the privileges of its Fellows guarded. In the interests of scientific progress it is to be hoped that the coöperation will become possible.

THE PLAGUE OF INGENUITY.

IN many ways human ingenuity is a plague to modern life and there is some excuse for the view of a great man who regarded the inventor of railways as a curse to his race. The truth probably is that no invention is at first perfect and we have to suffer from its transitory imperfections. We dare say that the motor-car is a triumph of locomotion but no one can deny that it has drawbacks. London has recently been invaded by the motor omnibus and most people recognise its convenience and advantage as regards its celerity of service, but this is terribly discounted by the stench and noise which apparently are inevitably attendant upon its progress. Until motor vehicles have wings, we have heard it said, they will always be an eyesore, an earsore, and a nosesore. While not prepared to accept that view, at any rate, as a condition of things likely to last, we must admit that the accessories of modern life in general are placing greater and greater strain on the faculties of the individual. His eyes are strained by the intense artificial lights, his ears are worried by the unnecessary din of the streets, and his nose is offended by the vapourisation of offensive fumes of oil or by the fœtid air of the "tube." That simpler life appeals to him more than ever which removes him from the maddening sphere of the inventors' activities. Still, after all, the human machine is wonderful in its power of adapting itself to a new environment and just as few now look upon the railway, as was formerly the case, as a really offensive invention so in time to come the present distresses inflicted upon us by modern ingenuity will, it is to be hoped, gradually disappear partly by the process of adaptation and partly by improvements resulting in mitigation of the kind of evils referred to. One thing at least may be said and that is, on no account should a modern invention be tolerated, however convenient it may be in one direction, unless it satisfies hygienic requirements.

EDWARD JENNER ON ANTIVACCINATIONISTS.

IT is curious to find that Edward Jenner believed in the power of Parliament to put an end to what we now call "the Antivaccination Movement." In an unpublished letter, the property of Mr. William J. Treadgold of Derby, Edward Jenner, writing under date Jan. 16th, 1807, says: "My movements will be regulated by those of the College of Physicians and the House of Commons. The former have not yet finished their inquiry, which will, when completed, be laid before the House. This inquiry will lay all the troublesome ghosts which have so long haunted the metropolis with their ox-faces and dismal hootings against vaccination. However, 'tis all for the best. You may depend upon it the new investigation will prove the touchstone of the vaccine discovery." The report of the College of Physicians was so strongly in favour of Jenner that the House of Commons voted him £20,000. On the continent, too, he was almost worshipped. A certificate signed by him took the place of a passport in some countries, while Napoleon the Great and the King of Spain released prisoners of war at his request. Nevertheless, the "ox-faces" at home were unabashed. *The Cow-pox Chronicle* seems to have been the antivaccinationist organ of that day. Baron refers feelingly to "its atrocious falsehoods, its coarse and disgusting ribaldry, and its impious scurrility." Vaccination was often a subject for debate. In March, 1808, the "British Forum" debating society solemnly discussed the following question: "Which has proved a more striking instance of the public credulity, the gas lights of Mr. Winsor or the cow-pox inoculation?" Both gas light and vaccination were "handed over to scorn and ignominy."

A CONFERENCE OF CHARITY ORGANISATION SOCIETIES.

WE understand that a conference of charity organisation societies will be held at Tunbridge Wells on June 11th, 12th, 13th, and 14th, and that invitations to it are being issued by the committee of the Tunbridge Wells Charity Organisation Society. There will be a reception by the Mayor at the town-hall on June 11th, at 8 P.M., and a garden party will be given by Miss Crothers at Southborough on June 12th. On June 12th, 13th, and 14th papers will be read on the following subjects: (1) the Royal Commission on Vagrancy Act (with special reference to Enforced Labour Colonies); (2) the Feeding of School Children; (3) Constructive Charity; and (4) Guilds of Help (adoption of the Elberfeld system). Each paper will be followed by a discussion. It is also proposed to hold a private meeting of members of charity organisation societies on June 14th, at 10.30 A.M., to consider the subject of Thrift. Arrangements will be made for an excursion to Penshurst Place and Lingfield Epileptic Training Home on the afternoon of June 13th. Colonel E. D. Newnham-Smith is the President of the Charity Organisation Societies Conference Committee. All communications should be addressed to Miss Rix, the honorary conference secretary, 32, Dudley-road, Tunbridge Wells.

POISONING BY PICRIC ACID.

CERTAIN remedies used in surgery occasionally produce symptoms caused by their absorption into the system. Amongst such substances iodoform and carbolic acid most frequently give rise to untoward phenomena. In THE LANCET of April 28th, p. 1175, we published the record of a case which occurred in the Radcliffe Infirmary, Oxford, in which picric acid applied to burns produced evidences of poisoning in the patient. Picric acid is trinitrophenol and is formed by the action of nitric acid on phenol. In this case the most important manifestations were referred to the skin and the urine, although the constitutional symptoms were severe. An eruption, in many respects resembling measles, appeared over part of the neck, the whole of the chest, the abdomen, and the back, the arms as far as the wrists, the front of the thighs, the calves, and the insides of the knees. It was absent, however, from the face and behind the ears. Picric acid has the effect after absorption of combining with the hæmoglobin of the blood corpuscles and of displacing the weaker combination in them of oxyhæmoglobin, thus preventing the normal metabolism of the tissues. Methæmoglobin is formed and can be recognised by its peculiar absorption band in the spectrum. Certain changes are also found in the blood corpuscles. Professor Erb found distinct nuclei in the red discs and free nuclei in the serum; the white blood corpuscles show a tendency to numerical increase. The urine is frequently red in colour; the poison is mainly eliminated by the kidneys and doubtless the changes in the urine are due to the reaction which occurs in the blood. The urine in this particular case was examined by Dr. W. Ramsden of the Oxford Physiological Department. The first sample examined was rich with some abnormal pigment. This pigment was carried down with the earthy phosphates precipitated by heat, the precipitate having a rich brown colour. The exact nature of the pigment could not be ascertained, but the tests for hæmatoporphyrin, methæmoglobin, and hæmatin proved negative. The case is well worthy of record. We are not aware of any evidence that has been brought forward of idiosyncrasy in respect of such drugs as picric acid, carbolic acid, or iodoform, though possibly it may exist. The occurrence of instances of poisoning by these substances naturally does not prohibit the use of such valuable medicaments but indicates that they must be employed with caution. We believe that no fatal case of poisoning by picric acid has occurred when the drug has been used for medicinal purposes, but in THE LANCET of August 5th, 1891, an instance was reported of a man who worked in a melinite factory and inhaled fumes of nitrous acid and volatilised picric acid. Severe dyspnœa ensued, with cough and spasm of the glottis. Picric acid was found in the urine. Parenchymatous nephritis followed and death ensued.

UNIVERSITY COLLEGE, LONDON (UNIVERSITY OF LONDON).

A COURSE of eight lectures on the Structure and Functions of the Central Nervous System, with special reference to the Brain Stem, will be given in the physiology department by Dr. W. Page May, Fellow and lecturer of the College, on Wednesdays at 5 P.M., beginning on Wednesday, May 16th. The syllabus of the lectures is as follows:—1. Elements of the Nervous System; Neurons; Methods of Investigation; Anterior and Posterior Spinal Roots. 2. Spinal Cord; General Structure; Conduction and Localisation. 3. Centres and Conducting Paths in the Medulla Oblongata. 4. The Pons; Origin of Cranial Nerves. 5. The Cerebellum. 6. The Mid-brain and Corpora Quadrigemina. 7. Optic Thalamus and Basal Ganglia. 8. Certain Motor and Sensory Paths; Summary. These lectures are open to all students of the University of London, also to qualified medical men on presentation of their cards and to such other persons as are specially admitted.

THE TOXIC EFFECT OF OZONE AND OTHER OXIDISING AGENTS ON LIPASE.

ON being asked to describe the odour of small quantities of ozone two out of six persons, not versed in chemistry, described it as similar to that of prussic acid. This reply led Mr. J. H. Kastle, Ph.D., to investigate the action of ozone on lipase, in order to determine whether ozone, like hydrocyanic acid, was a protoplasmic poison. The results of this work are published by the United States Government in an official bulletin.[1] The ozone used in the experiments was obtained by the electrolysis of acidulated water and the lipase from the liver of the hog. The effect of ozone on lipase was determined by exposing a clear solution of the ferment to the action of a known weight of ozone at the ordinary temperature for a given time. It was noticed that after the lapse of 24 hours the odour of ozone had disappeared and the solution had become cloudy and contained a perceptible coagulum. The lipolytic action of this solution was then ascertained by determining the weight of ethyl butyrate which it was capable of hydrolysing under the conditions described in the paper. It was found that an amount of lipase capable of hydrolysing 0·058 gramme of ethyl butyrate in six hours was practically destroyed when exposed to the action of 1·009 milligrammes of ozone for 40 minutes. These results are in accord with those of Sigmund who has shown that ozone is poisonous to invertase, pepsin, emulsin, and other ferments. Dr. Kastle extended his inquiry to other oxidising agents and antiseptic substances and found that so far as their toxicity or non-toxicity towards lipase is concerned they fall into three distinct groups. The first group includes silver nitrate, iodic acid, formic aldehyde, the cresols, hydrocyanic acid, potassium nitrite, and succinic acid, which are practically non-toxic. Mercuric chloride, chromic acid, copper sulphate, and perosmic acid form the second group and are moderately toxic. The last group consists of powerfully toxic substances, including ozone, chlorine, bromine, sodium fluoride, iodine cyanide, and potassium permanganate. It is of interest to note that the first two groups contain a number of substances which are highly toxic to many living forms, whereas with one exception the last group is composed of powerful oxidising agents.

THE ROYAL INSTITUTE OF PUBLIC HEALTH.

THE lecture arrangements at this institute for the summer session of the current year are as follows. Dr. Carl Prausnitz of Breslau, demonstrator of bacteriology and comparative pathology in the institute, is giving a course of three lectures upon the Bacteriology of Water and Milk and upon Tuberculosis. The first lecture was delivered on May 9th and the other two will be delivered on May 16th and 23rd respectively, in the lecture theatre of the Institute, 37, Russell-square, at 5 P.M. Dr. William R. Smith is giving a course of five lectures on the Law of Public Health. The first lecture was delivered on May 8th and the remaining four will be delivered on May 15th, 22nd, 29th, and June 5th, at 5 P.M. Mr. Charles E. Harris, Ph.D., demonstrator of chemistry in the institute, will deliver three lectures on the Manufacture and Sophistication of Potable Spirits. The lectures will be delivered on successive Tuesdays at 5 P.M., commencing on June 12th. The Harben lectures for 1906 will be delivered by Professor Elie Metchnikoff of the Pasteur Institute, Paris. The lectures will be given in French in the lecture theatre of the Royal Institute of Public Health, 37, Russell-square, London, W.C., on Friday, May 25th, Monday, May 28th, and Wednesday, May 30th, at 5 P.M. Lecture I. deals with the Hygiene of the Inner Tissues of the Organism; Lecture II. with the Hygiene of the Intestinal Tract; and Lecture III. with Syphilis. The attendance of those interested is invited.

THE CHILDREN'S HOME HOSPITAL, BARNET.

THIS excellent institution is in great need of funds for rebuilding. It was founded in 1890 and provides for that very class of cases which the ordinary convalescent homes as a rule must exclude—namely, those which require careful supervision and special surgical treatment. The 14 beds, which can be increased to 15 on emergency, are always full and the weekly payment for a child is only 3*s*. 6*d*. The authorities of the hospital are in a position to purchase half an acre of land on Hadley Green upon which to rebuild the hospital but a sum of £2500 is urgently needed. The hospital is at present established in an ordinary house which is by no means an ideal building for a hospital. For instance, there is only one room for the use of the staff and the patients, and the two nurses have to occupy the same bedroom and have no sitting-room, a circumstance which makes it difficult to obtain and to keep efficient nurses. What is wanted, to quote the words of one of the honorary consulting surgeons, "is a building in the bungalow style, in which every window opens on to a veranda, so that the children can be wheeled on their beds into the open air. This is absolutely impossible in the present building, which is a simple dwelling-house and does not even possess the ordinary amount of garden space of a suburban villa." The patients of this hospital belong for the most part to a class for whom it is most difficult to find treatment. As a rule, they are tuberculous children suffering from chronic affections of the joints or rickety children suffering from chronic forms of malnutrition. These are just the cases which the ordinary convalescent homes naturally will not take. This hospital does excellent work and we commend this appeal to the notice of our readers, in the hope that they may influence those whom they may come across to help to provide the much-needed sum of £2500.

---

[1] No. 26, Hygienic Laboratory, U S Public Health and Marine Hospital Service, Washington Pp 51 1906.

THE CENTRAL MIDWIVES BOARD.

AT its meeting on May 3rd the Central Midwives Board was occupied in hearing various charges brought against midwives for contravening the rules of the Board. In the cases of six women their names were ordered to be taken off the roll of midwives. In five of these cases the midwives had failed to carry out the regulations of the Board with regard to the proper use of antiseptics, the proper care of the patients, the keeping of a register, or the neglect to send for medical assistance when it was necessary for them to do so. In one of the cases the midwife was convicted of drunkenness on several occasions. In the remaining case the midwife was censured and it was ordered that a report should be furnished of her conduct in three months' time. In this instance the woman was accused of neglecting to tie the cord properly, thereby causing the death of the infant; she had failed also to notify the death of the child to the local supervising authority and she did not keep a register of cases as required by the rules of the Board. We note with satisfaction the fact that the Board is making good use of the disciplinary powers conferred on it in removing from the roll the names of midwives who fail to carry out the rules and regulations laid down by it. The omission on the part of midwives to provide themselves with proper appliances or to carry out proper antiseptic precautions is a very serious offence and should be punished with all severity. It is to be hoped that local supervising authorities will not be slow in reporting to the Board all cases of breaches of the rules of too serious a nature for them to deal with locally. In this way only will it be possible to convince midwives all over the country that they will neglect the rules of the Board at their peril and that they run the very serious risk of having their names removed from the roll if they are reported to the central authority. For this purpose the loyal coöperation of all local supervising authorities is of the utmost importance not only in attending to the proper supervision of the midwives in their district but also in seeing through their officers that the Act and its regulations are efficiently carried out.

A COURSE of four lectures on clinical surgery will be delivered at the London Hospital Medical College (University of London) by Mr. Jonathan Hutchinson, F.R.S., emeritus professor of clinical surgery to the hospital, on the following dates: June 12th, on the Transmission of Syphilis to the Third Generation; June 19th, on Syphilis and Tuberculosis; June 26th, on Tuberculosis and Diseases of the Skin; and July 3rd, on Diseases of the Skin caused by Insects. The lectures will be given in the clinical theatre at 3 o'clock. They are free to all students of the University and to medical graduates.

THE annual meeting of the Dermatological Society of Great Britain and Ireland will take place at 11, Chandos-street, Cavendish-square, London, W., on Wednesday, May 23rd, at 4.30 P.M. Dr. Sabouraud will give the oration on the Radio-therapeutics of Ringworm in the Municipal Laboratory of the City of Paris at the Hospital of St. Louis. The President and council hope that members of the profession interested in Dr. Sabouraud's work will honour the society by their presence at the meeting.

THE annual dinner of the British Balneological and Climatological Society will be held at the Imperial Restaurant, Regent-street, London, W., on May 16th, at 7.30 P.M. Dr. F. T. Roberts will be the guest of the society. Previously to the dinner an ordinary meeting will be held at 20, Hanover-square, at 5.30 P.M., when Dr. Roberts will deliver an address entitled "Some General Comments on Balneology and Associated Methods and on Spas."

Dr. Auguste Broca, president of the Society of Pediatrics and surgeon to the Hôpital des Enfants Malades, Paris, will deliver the Wightman lecture before the Society for the Study of Disease in Children, on the subject of Appendicitis, at the rooms of the Medical Society of London, 11, Chandos-street, London, W., on Friday, May 18th, at 5.30 P.M. The lecture is open to all medical men.

Sir Henry D. Littlejohn, LL.D., will preside at the next dinner of the Edinburgh University Club of London, which will take place on Wednesday, May 16th, at the Criterion Restaurant, Piccadilly-circus, London, W. Amongst those who have accepted invitations to be present are Sir William H. Broadbent, Sir Thomas Stevenson, Sir Shirley F. Murphy, and Colonel Greig.

WE are informed that the Long Vacation classes to be held this year in the medical school of the University of Cambridge will, besides the ordinary classes in general pathology and pharmacology, include a series of shorter courses dealing with more advanced work. Further particulars are given in our advertising columns.

AN extraordinary general meeting of the National League for Physical Education and Improvement will be held at Denison House, Vauxhall Bridge-road, near Victoria Station, London, on Wednesday, May 16th, at 4 P.M. The Bishop of Ripon will preside. All members of the Twentieth Century League have been invited.

THE Medical Society of London will hold a conversazione in the rooms of the society, 11, Chandos-street, Cavendish-square, London, W., on Monday, May 21st, at 8.30 P.M. At 9 o'clock an oration will be delivered by Professor Kocher of Berne, the subject being "Some Contributions to the Pathology of the Thyroid Gland."

THE annual meeting of the National Health Society will be held at Grosvenor House by the kind permission of His Grace the Duke of Westminster on May 21st at 4 P.M. The Right Hon. the Earl of Derby will preside.

THE next session of the General Medical Council will begin on Tuesday, May 22nd, at the office of the Council, 299, Oxford-street, London, W., at 2 P.M. The President, Dr. Donald MacAlister, will be in the chair.

Professor Kocher of Berne is to deliver the annual address of the Cardiff Medical Society on May 25th. He has chosen as his subject Graves's Disease.

ROYAL HOSPITAL, RICHMOND, SURREY.—Mrs. Swan of Teddington, widow of the late Mr. B. B. Swan, has contributed a sum of £4000 for the building and equipment of two new ophthalmic wards and the necessary accommodation for nurses at this hospital. The buildings will be known as the Benjamin Bousfield Swan Wing. In order that the income of the hospital may not suffer by the demolition of certain cottage property which belongs to the hospital Mrs. Swan has generously contributed a further sum of £2000 to the endowment fu

THE EARL OF CROMER'S REPORT ON EGYPT FOR 1905.

Lord Cromer's annual report on Egypt is even longer than it was last year but, as usual, it can be read from end to end with both pleasure and profit. In the opening paragraph we are told that 10,160 copies of the last report were distributed, 4800 in Arabic, 4442 in English, and 918 in French, so the author is perfectly right in concluding that a sufficient interest in his reports is shown by the public to justify the continuance of their publication.

In his first chapter Lord Cromer deals with "the system generally known as the *régime* of the capitulations in Egypt." This is a matter of the highest interest to sanitarians, for under the capitulations as at present enforced it is perfectly impossible to safeguard the public health in Egypt with complete success. The officials of the sanitary department are heavily handicapped in their contest with preventable diseases, the infecting germs being unfortunately uninfluenced by considerations to which international jealousy attaches overweening importance. The health officers cannot do their work properly; and when epidemics gain ground they are not only exposed to undeserved blame but also have to support the chagrin which attends on defeated effort. A good illustration of this hardship is shown in the following extract from a report by Sir Horace Pinching which is quoted by Lord Cromer: "46 cases of small-pox occurred, half of which were among Europeans, and were entirely due to the neglect of vaccination on the part of the poorer classes of Europeans." With the natives of Egypt vaccination is compulsory, but it cannot be enforced among foreigners who are not even compelled to declare that they have conscientious objections to it. It is probably, therefore, through sheer carelessness that their children remain a standing source of danger to the natives among whom they live.

Lord Cromer's task is a difficult one. At present, he says, no change can be made in any law applicable to Europeans without the unanimous consent of nearly all the Powers of Europe and of the United States of America, and experience has shown that even in relatively minor matters the process is so tedious and beset with so many difficulties that as often as not the Egyptian Government abandons the negotiations in despair of ever arriving at any practical result. He accordingly proposes that with the exception of Great Britain all the Powers shall cease to exercise legislative functions. The scheme which he suggests is formulated in 17 clauses but of these the second contains the essence of the whole. It provides for the creation of a separate Council composed wholly of subjects of the Powers which instituted the mixed tribunals, and legislation passed by a majority of this Council when promulgated by the Egyptian Government with the assent of His Britannic Majesty's Government shall be binding on all foreigners resident in Egypt. In one of the minor clauses it is laid down that the preservation of Egypt from disease should lie entirely within the functions of the Egyptian Government which would have to submit any proposed measures that it might wish to adopt to the European and native branches of the legislature unless it were in its power to enact those measures without special legislation, while in another it is proposed that an engagement should be entered into by both the British and Egyptian Governments that every reservation in favour of British subjects should enure for the benefit of the subjects of other Powers.

In the interests of the *suprema lex* it is devoutly to be wished that Lord Cromer's suggestions may be promptly adopted and that ere long the maintenance of potential centres of disease in the midst of the Egyptian population may be constituted a punishable offence against the public security as great as if the persons responsible for them had scattered dynamite broadcast where it was liable to be exploded.

As regards medical and sanitary affairs generally Lord Cromer's report indicates some progress but the great question of the drainage of Cairo is not mentioned. Should the capitulations be abrogated it ought then to become possible to proceed with this essential work which was first proposed and accepted theoretically in 1890. It is owing to the apathy or ill-will of the Powers that the project has remained in suspense for so many years. Writing in Lord Cromer's report for 1894 Sir William Garstin stated that a law empowering sanitary inspection and expropriation of land was required before the Cairo drainage scheme could be undertaken and that the Powers had not consented, although a formal application to them to do so had been made in July, 1893. That the sewerage of Cairo is a matter of extreme urgency is shown by the death-rate. According to the returns for the first fortnight in January last (which should be about the healthiest part of the year) the mortality among the native and European inhabitants respectively was at the rate of 34·0 and 31·7 per 1000 per annum. Typhoid fever[1] and other affections usually associated with defective sanitation are still very prevalent in Cairo in spite of the greatly improved surface cleanliness, the excellent water-supply, and the magnificent climate. The longer the drainage question is postponed the more expensive it will become. Every year streets are being paved and asphalted. Last year, Lord Cromer says, £E.27,000 were spent on these improvements. The advantage, for the moment, is no doubt considerable but when sewers are laid the work will have to be done a second time. At the present time 47 per cent. of the total area of roads in Cairo are entirely unpaved, while 28 per cent. more are merely macadamised with soft limestone. The sooner the drainage works are undertaken the better it will be from every point of view, sanitary or financial.

In his chapter on Public Health Lord Cromer gives some interesting information with regard to the progress which has been effected in connexion with medical and sanitary affairs. The number of in-patients treated in the Government hospitals during 1905 was 29,237, against 27,921 in 1904; 125,128 out-patients were treated in the hospitals and dispensaries. About £E 25,000 have been provided in the estimates for the current year for the construction of new, or for the improvement of old, hospitals. Of this sum £E.9000 are to be spent on a hospital for contagious diseases at Alexandria. Owing to a want of accommodation in the Abbassieh Lunatic Asylum (the only asylum in Egypt) it is still necessary to overcrowd the building and also to discharge patients prematurely. There is good reason to expect, however, that before long additional accommodation for about 300 lunatics will become available at Abbassieh, bringing the total number of beds up to 812, and also that a second asylum, to contain 600 beds, will be built in a suitable position a few miles to the north of the present one. For the construction of the new establishment about £E.107,000 will be required, and in order that a commencement may be made a sum of £E.20,000 has been included in this year's estimates. On the subject of the water-supply of towns Lord Cromer has a good deal to say. Alexandria is now well supplied. Since last June much of the water that is supplied to Cairo has been pumped from artesian wells sunk to the north of the town. More wells are in process of being sunk and eventually the whole district will be supplied from this source. Mansourah has been given wholesome water at a cost of £E.26,000. The waterworks at Damietta are nearly completed; when finished the town of Esbet-el-Borg will receive its supply from them and water will also be furnished to Ras-el Bar, a fashionable resort at the *embouchure* of the Nile, opposite Esbet-el-Borg, where between 3000 and 4000 visitors assemble during the summer months, living in grass huts, and enjoying unrivalled sea-bathing and cool sea breezes. Plans are also being prepared for waterworks at Zagazig, Menouf, Mehalla-el-Koubra, Zifteh, and Mit Ghamr, and it is expected that work will be commenced at these places in the course of the current year. In the opinion of the head of the Egyptian Sanitary Department, Sir Horace Pinching, the provision of a pure water-supply is "the most important step taken up to the present by the Government in the direction of improving the general hygienic condition of the country." As a rule, the procedure has been greatly appreciated by the population and petitions are constantly received begging the Government to extend the system to the petitioners' towns; but, on the other hand, prejudices against the use of well-water still exist. Sir H. Pinching has been assured that the women often think that it causes their hair to fall off.

Lord Cromer's remarks under the head of malaria are very interesting. "I have alluded in former reports," he says, "to the very successful results obtained at Ismailia in combating malaria by the adoption of the system initiated by Major Ross. During the past year the campaign against mosquitoes was commenced at Suez. The results have been distinctly satisfactory. The number of in-patients treated in the Government hospital for malarial affections during 1905 was 91, as compared to 118 in 1904, whilst the number of out-patients fell from 405 to 260." Dr. J. E. Cresswell reports: "This does not show the real benefit, great as it is. During the last few years an intimate knowledge of the people has led me to estimate that in the Fagalla quarter 25 per cent. of the inhabitants were infected, 75 per cent. in the Arbaeen and 100 per cent. in the gardens. Also, one member of a family would come to the out-patients' department and take home quinine to the other sick members of the family; this year they said there was no fever so far as the town was concerned." In spite of this improvement, continues Lord Cromer, it will be necessary to drain the marshes near Suez and to adopt other remedial measures before the fever can be extirpated completely. A campaign against mosquitoes is also being instituted at Port Said.

---

[1] The recent death in Cairo of Sir Edwin Palmer, who for some years was financial adviser to the Egyptian Government, was caused by typhoid fever.

(To be concluded.)

HAMPSTEAD GENERAL HOSPITAL.

A SUCCESSFUL conference of the local profession on the management of the Hampstead General Hospital took place on May 5th, at the Hampstead Conservatoire, under the auspices of the Hampstead division of the British Medical Association. Mr. F. R. HUMPHREYS, chairman of the division, presided.

There were many members of the Hampstead division present, as well as some members of the St. Pancras division (which had agreed to the motions to be placed before the conference), and many local medical practitioners who did not belong to the Association.

The proceedings opened by the CHAIRMAN calling upon the honorary secretary of the Hampstead division to read the resolution of the division, passed on April 6th, convening the conference.

The CHAIRMAN then gave a short address explaining the condition of things which had led up to the present meeting. He pointed out that the hospital was founded under the Companies Act, as a limited company, in 1882, and gave extracts from the memorandum and articles of agreement which showed that the objects for which it was started were "the providing of a home hospital and nursing institute for the benefit of persons who are unable to obtain in their own homes the accommodation, care, nursing, and attention which they require when overtaken by sickness or accident" and that it "is designed primarily for the benefit of persons residing in Hampstead," permitting persons residing outside the borough to "be admitted to the benefits of the hospital, subject to such restrictions and upon such terms as the council shall from time to time think fit." He pointed out that free beds were not provided until 1893 and that the out-patient department had not been started until 1896. He observed that there were few or no persons in Hampstead (except paupers) who were unable to pay the fees of the provident dispensary, which for 11*d.* per month provided a man and his wife and unlimited children with medical attendance during sickness. The health of Hampstead was shown by the report of the acting medical officer of health of the borough, Mr. F. E. Scrase (on whose report, just issued, he begged to congratulate him), to be considerably better than any other part of the County of London, and the same report mentioned that there were eight public institutions for the sick and infirm within the borough and that 40 similar institutions outside it had received Hampstead residents during 1905. He added that within three miles of the Hampstead General Hospital there were seven general hospitals and at least 15 special hospitals, nearly all of which had out-patient departments; there were other neighbouring medical institutions in addition to these. So that neither Hampstead nor the surrounding district appeared to be in want of a general hospital in Hampstead. However, he recognised that that institution existed and had to be made the best of. In December last the hospital had made a new start in the new building on Haverstock-hill and was presented with the sum of £20,000 to pay off the expense of rebuilding. The King's Fund had at different times given £4500 to the same funds and its executive had recently stated that they were prepared to recommend a further donation of £5000 to the same object, coupled with the suggestion that a consulting staff should be appointed. The existing staff consisted of general practitioners who did their work to everybody's satisfaction. The chairman stated most emphatically that the present agitation was not in any way directed against the medical staff of the hospital and that all such action had been most carefully excluded from the earlier proceedings. There was no ethical question touched; only large issues were under discussion.

Mr. H. W. ARMIT then moved motion 1 on the agenda:—

> That an out-patient department in Hampstead is unnecessary.

The motion was seconded by Dr. G. D. PIDCOCK.

Dr. E. COLLINGWOOD ANDREWS, a member of the staff of the hospital, speaking on behalf of his colleagues and himself, agreed with the last four of the motions before them, but asked for clear evidence on the first motion, such as could be investigated, that the out-patient department was abused. He was not prepared to agree that there were no poor in Hampstead. He said that disfranchisement followed sick attendance under the Poor-law and if out-patients were to be referred to the relieving officer this should be remembered.

Dr. J. FORD ANDERSON spoke to the effect that out-patient departments were unnecessary and that in Hampstead they were a superfluity.

Dr. M. DUTCH pointed out that it was difficult to give the names and addresses of persons who were believed to be ineligible for treatment at the out-patient department at which they had obtained relief. Such information might lead to an action for libel.

Dr. WALTER SMITH said that medical relief did not disfranchise, that 75 per cent. of the patients attending at the out-patient department of the Hampstead Hospital were said to come from St. Pancras, and his experience as a guardian there was that large numbers of those who, on account of the possession of means, were refused relief under the Poor-law went to the out-patient departments of hospitals and improperly obtained treatment there. He had known Hampstead for 30 or 40 years and there was less poverty there than anywhere else in London.

Mr. H. C. PARSONS moved as an amendment:—

> That motion 1 be postponed until adequate reasons had been given by the secretary (of the meeting) to the staff which they could put before the council and cause the closing of the out-patient department.

He said that he moved this amendment, as without the coöperation of the staff nothing could be done with the hospital. No adequate reasons were given in motion 1 for the closure of that department.

Dr. W. COODE ADAMS seconded the amendment. He said that the motion touched upon difficult and dangerous ground and that it was necessary to remember that the lay public had the last word. He was in general agreement with the motion but further investigation was required.

Mr. SCRASE (one of the staff of the hospital) supported the amendment and said that the hospital had an almoner who investigated the claims of the patients attending the out-patient department and that the latter were also required to produce "letters." The staff were quite willing to coöperate in abolishing it when it was proved that the out-patient department was abused. The Provident Dispensary was very poorly equipped for treating patients.

Dr. W. HEATH STRANGE said that so far from the Provident Dispensary being badly equipped some £1500 had been spent on it.

Mr. E. T. AYDON SMITH pointed out that the greatest part of the opposition to the closure of the out-patient department lay in the fact that the Hospital Saturday and Sunday Funds made grants depending upon the numbers of patients attended at the hospital and that the out-patients added very largely to the sum total. He had had personal experience of one hospital where various dental operations on a patient's mouth, given at the same sitting, were each reckoned as different attendances.

Dr. H. SHARMAN pointed out the enormous temptation to hospital authorities to keep up a large out-patient department. There were many large hospitals near Hampstead to which out-patients could go and where, at any rate, even if ineligible for attendance, they might be made use of for teaching purposes. He thought that the Hampstead Hospital was an unnecessary institution altogether but recognised its existence.

The amendment was then put to the vote and lost by 16 to 34. On motion 1 being put to the vote it was carried by 40 to 7. A motion was then made that the remaining four motions should be put *en masse*. This was agreed to and the motions as follow were thereupon put before the meeting:—

2. That the casualty department be kept distinct from any other department and that casualty patients, if not suitable for admission, be seen once and thereon be referred to private practitioners, provident dispensaries, or Poor-law authorities.
3. That there be greater facilities for general practitioners of the neighbourhood to attend in patients.
4. That there should be a *service* limit as well as an age limit to appointments to the medical staff.
5. That the outside medical profession should be *adequately* represented on the board.

Dr. L. G. GLOVER (one of the hospital staff) said that motion 2 was already carried out in practice and that when the new block was erected motion 3 would be carried out. If more pay beds (in which medical practitioners not on the staff could attend their own patients) were desired that would be agreed to. There would be general agreement about motion 4. With regard to motion 5, that would entail re-organisation of the hospital management, as there was no representation on that body, except from the Ladies' Association, which was a part of the hospital organisation.

Dr. ANDERSON spoke of the dangers of initial errors and said that as there appeared to be a medical re-organisation of the hospital in prospect it would be well to restart properly. He was of opinion that some of the motions did not go far enough; that there was a large amount of abuse, perhaps not very serious at present, which might easily extend itself. No medical staff was required for the hospital. A list of medical men ready to act if called upon in emergency was all that was required. It was essential that the local profession should be represented on the board of management by men not on the staff.

Mr. K. J. DOUGALL said that every local medical man ought to have an opportunity of attending his patients, to whatever part of the hospital they might be admitted. A rota of practitioners appointed for a month or so was all that was required.

Motions 2 to 5 inclusive were then passed *nemine contradicente*.

The SECRETARY then read the letter which had been sent out by the authorities of the Hampstead Hospital relative to the appointment of a consulting staff and quoting a letter from the executive of King Edward's Hospital Fund recommending the appointment of a consultant staff on the ground of the importance of the Hampstead General Hospital. The questions which the medical practitioners, addressed by the hospital, were asked to reply to included one in which a pure general practitioner staff was to be appointed as at present; a second as to an acting staff of consultant physicians and surgeons; and a third as to a mixed staff, composed partly of consultants and partly of general practitioners. The fourth asked for opinions as to the effect upon the popularity of the hospital likely to result from the change from general practitioner to consultant staff.

A motion was then proposed by Dr. SHARMAN and seconded by Mr. DOUGALL:—

> That the work of the hospital be carried on by local practitioners but in addition a limited list of surgeons, physicians, and specialists not belonging to the neighbourhood be kept for consulting purposes.

Dr. H. OPPENHEIMER moved as an amendment—

> That it is desirable both in the interest of the district and of the hospital itself that the Hampstead Hospital be carried on as a purely local institution, not as a large general hospital, and that therefore an acting staff of consultants is not in accordance with the spirit of its constitution.

This was seconded by Mr. R. HENSLOWE WELLINGTON.

Dr. COLLINGWOOD ANDREWS said that the hospital medical staff dissociated themselves entirely from the circular. They had had nothing whatsoever to say to it and were not consulted about it.

Mr. E JESSOP said that the hospital staff had come there in an evidently friendly spirit, desirous of meeting the local medical profession not on the staff, and that it was desired to retain the present staff in office. There was no such thing as a pure consultant in London, they were merely rival practitioners, and he could not support the appointment of a staff of this nature.

Dr. SHARMAN said that it might be desirable to call in pure surgeons in the case of the performance of major operations at the hospital.

The CHAIRMAN remarked that this was done at the Willesden Cottage Hospital.

Dr. FORD ANDERSON mentioned the analogous case in respect to the Putney General Hospital as proposed. The local profession there were not desirous of a staff of consultants, but the terms of the deed of gift to that institution required the founding of a general hospital within a limited time or the money would go elsewhere. A compromise permitting a consulting staff to perform operations seemed likely to be the solution of the difficulty in the Putney case.

Dr. L. GLOVER pointed out that the Hampstead Hospital already had a staff of consulting physicians and surgeons. He said that the reason why there was so much dislike to the performance of surgery by general practitioners was that general practitioners had not formerly had the opportunity of performing many operations.

The CHAIRMAN inquired whether there was any limit to the operations performed in the Hampstead Hospital and whether the hospital rules required a consultation to be held prior to an operation. He pointed out that the absence of any restrictions in such matters might well account for the suggestion of the executive of the King's Fund for the substitution of an acting staff of consultants.

Dr. L. GLOVER replied that there were no such rules in force, either to limit the operations performed or as to their being preceded by a consultation. In practice eight out of ten of the operations were preceded by a consultation.

The amendment was then put to the meeting and carried with one dissentient. A rider was then moved by Mr. JESSOP:—

> That the work of the hospital be carried on by local practitioners, but in addition a limited list of physicians, surgeons, and specialists not belonging to the neighbourhood be appointed, who shall give their services in consultation as desired by the acting staff of the hospital.

But it was felt by the meeting that the rider introduced matters which it was desirable to avoid and the rider was withdrawn.

A protest was made by Mr. W. B. PEARSALL against the exclusion of Irish degrees from the medical qualifications required to be held by the staff prior to appointment.

On "the steps to be taken to carry into effect the objects of this conference," Dr. OPPENHEIMER moved that three or four members of the present meeting should be elected to coöperate with the local division of the British Medical Association and to take all steps deemed advisable, with power to add to their number. This was seconded by Dr. E. CLAUDE TAYLOR and carried *nemine contradicente*.

The following gentlemen were then nominated and agreed to: Dr. J. R. Whait, Dr. Walter Smith, Dr. Taylor, and Mr. Parsons.

The meeting terminated with a vote of thanks to the Chairman.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE London and Counties Medical Protection Society held its annual general meeting, under the chairmanship of Dr. G. A. HERON, on May 4th, at 31, Craven-street, Strand, London, W.C.

The annual report gave many examples of the value to a member of the medical profession of belonging to a defence society, the following cases taken being good instances. A consulting physician received a demand from the solicitors of a patient for the return of all fees, subject to an action for damages for unskilful treatment. It seemed possible that the physician's diagnosis of an obscure ailment had been wrong but the complainant's solicitors were informed that the fees would not be returned and that the society would defend its member in any legal proceedings. No further action took place. Another member received a letter from the husband of a patient, accusing the member of causing his patient prolonged suffering by an alleged error in treatment, the treatment consisting in a bath of a pound of potassium sulphate to 30 gallons of water, when a troublesome dermatitis supervened. The member was advised how to reply and he was recommended to enforce payment of his fees, applying to the society for further assistance if occasion arose. No further assistance from the society was required. In another, case a claim was malaria by the adoption of the system initiated by Major Ross. During the past year the campaign against mosquitoes was commenced at Suez. The results have been distinctly satisfactory. The number of in-patients treated in the Government hospital for malarial affections during 1905 was 91, as compared to 118 in 1904, whilst the number of out-patients fell from 405 to 260." Dr. J. E. Cresswell reports: "This does not show the real benefit, great as it is. During the last few years an intimate knowledge of the people has led me to estimate that in the Fagalla quarter 25 per cent. of the inhabitants were infected, 75 per cent. in the Arbaeen and 100 per cent. in the gardens. Also, one member of a family would come to the out-patients' department and take home quinine to the other sick members of the family; this year they said there was no fever so far as the town was concerned." In spite of this improvement, continues Lord Cromer, it will be necessary to drain the marshes near Suez and to adopt other remedial measures before the fever can be extirpated completely. A campaign against mosquitoes is also being instituted at Port Said.

(To be concluded.)

HAMPSTEAD GENERAL HOSPITAL.

A successful conference of the local profession on the management of the Hampstead General Hospital took place on May 5th, at the Hampstead Conservatoire, under the auspices of the Hampstead division of the British Medical Association. Mr. F. R. Humphreys, chairman of the division, presided.

There were many members of the Hampstead division present, as well as some members of the St. Pancras division (which had agreed to the motions to be placed before the conference), and many local medical practitioners who did not belong to the Association.

The proceedings opened by the Chairman calling upon the honorary secretary of the Hampstead division to read the resolution of the division, passed on April 6th, convening the conference.

The Chairman then gave a short address explaining the condition of things which had led up to the present meeting. He pointed out that the hospital was founded under the Companies Act, as a limited company, in 1882, and gave extracts from the memorandum and articles of agreement which showed that the objects for which it was started were "the providing of a home hospital and nursing institute for the benefit of persons who are unable to obtain in their own homes the accommodation, care, nursing, and attention which they require when overtaken by sickness or accident" and that it "is designed primarily for the benefit of persons residing in Hampstead," permitting persons residing outside the borough to "be admitted to the benefits of the hospital, subject to such restrictions and upon such terms as the council shall from time to time think fit." He pointed out that free beds were not provided until 1893 and that the out-patient department had not been started until 1896. He observed that there were few or no persons in Hampstead (except paupers) who were unable to pay the fees of the provident dispensary, which for 11*d.* per month provided a man and his wife and unlimited children with medical attendance during sickness. The health of Hampstead was shown by the report of the acting medical officer of health of the borough, Mr. F. E. Scrase (on whose report, just issued, he begged to congratulate him), to be considerably better than any other part of the County of London, and the same report mentioned that there were eight public institutions for the sick and infirm within the borough and that 40 similar institutions outside it had received Hampstead residents during 1905. He added that within three miles of the Hampstead General Hospital there were seven general hospitals and at least 15 special hospitals, nearly all of which had out-patient departments; there were other neighbouring medical institutions in addition to these. So that neither Hampstead nor the surrounding district appeared to be in want of a general hospital in Hampstead. However, he recognised that that institution existed and had to be made the best of. In December last the hospital had made a new start in the new building on Haverstock-hill and was presented with the sum of £20,000 to pay off the expense of rebuilding. The King's Fund had at different times given £4500 to the same funds and its executive had recently stated that they were prepared to recommend a further donation of £5000 to the same object, coupled with the suggestion that a consulting staff should be appointed. The existing staff consisted of general practitioners who did their work to everybody's satisfaction. The chairman stated most emphatically that the present agitation was not in any way directed against the medical staff of the hospital and that all such action had been most carefully excluded from the earlier proceedings. There was no ethical question touched; only large issues were under discussion.

Mr. H. W. Armit then moved motion 1 on the agenda:—

> That an out-patient department in Hampstead is unnecessary.

The motion was seconded by Dr. G. D. Pidcock.

Dr. E. Collingwood Andrews, a member of the staff of the hospital, speaking on behalf of his colleagues and himself, agreed with the last four of the motions before them, but asked for clear evidence on the first motion, such as could be investigated, that the out-patient department was abused. He was not prepared to agree that there were no poor in Hampstead. He said that disfranchisement followed sick attendance under the Poor-law and if out-patients were to be referred to the relieving officer this should be remembered.

Dr. J. Ford Anderson spoke to the effect that out-patient departments were unnecessary and that in Hampstead they were a superfluity.

Dr. M. Dutch pointed out that it was difficult to give the names and addresses of persons who were believed to be ineligible for treatment at the out-patient department at which they had obtained relief. Such information might lead to an action for libel.

Dr. Walter Smith said that medical relief did not disfranchise, that 75 per cent. of the patients attending at the out-patient department of the Hampstead Hospital were said to come from St. Pancras, and his experience as a guardian there was that large numbers of those who, on account of the possession of means, were refused relief under the Poor-law went to the out-patient departments of hospitals and improperly obtained treatment there. He had known Hampstead for 30 or 40 years and there was less poverty there than anywhere else in London.

Mr. H. C. Parsons moved as an amendment:—

> That motion 1 be postponed until adequate reasons had been given by the secretary (of the meeting) to the staff which they could put before the council and cause the closing of the out-patient department.

He said that he moved this amendment, as without the coöperation of the staff nothing could be done with the hospital. No adequate reasons were given in motion 1 for the closure of that department.

Dr. W. Coode Adams seconded the amendment. He said that the motion touched upon difficult and dangerous ground and that it was necessary to remember that the lay public had the last word. He was in general agreement with the motion but further investigation was required.

Mr. Scrase (one of the staff of the hospital) supported the amendment and said that the hospital had an almoner who investigated the claims of the patients attending the out-patient department and that the latter were also required to produce "letters." The staff were quite willing to coöperate in abolishing it when it was proved that the out-patient department was abused. The Provident Dispensary was very poorly equipped for treating patients.

Dr. W. Heath Strange said that so far from the Provident Dispensary being badly equipped some £1500 had been spent on it.

Mr. E. T. Aydon Smith pointed out that the greatest part of the opposition to the closure of the out-patient department lay in the fact that the Hospital Saturday and Sunday Funds made grants depending upon the numbers of patients attended at the hospital and that the out-patients added very largely to the sum total. He had had personal experience of one hospital where various dental operations on a patient's mouth, given at the same sitting, were each reckoned as different attendances.

Dr. H. Sharman pointed out the enormous temptation to hospital authorities to keep up a large out-patient department. There were many large hospitals near Hampstead to which out-patients could go and where, at any rate, even if ineligible for attendance, they might be made use of for teaching purposes. He thought that the Hampstead Hospital was an unnecessary institution altogether but recognised its existence.

The amendment was then put to the vote and lost by 16 to 34. On motion 1 being put to the vote it was carried by 40 to 7. A motion was then made that the remaining four motions should be put *en masse*. This was agreed to and the motions as follow were thereupon put before the meeting:—

> 2. That the casualty department be kept distinct from any other department and that casualty patients, if not suitable for admission, be seen once and thereon be referred to private practitioners, provident dispensaries, or Poor-law authorities.
> 3. That there be greater facilities for general practitioners of the neighbourhood to attend in patients.
> 4. That there should be a *service* limit as well as an age limit to appointments to the medical staff.
> 5. That the outside medical profession should be *adequately* represented on the board.

Dr. L. G. GLOVER (one of the hospital staff) said that motion 2 was already carried out in practice and that when the new block was erected motion 3 would be carried out. If more pay beds (in which medical practitioners not on the staff could attend their own patients) were desired that would be agreed to. There would be general agreement about motion 4. With regard to motion 5, that would entail re-organisation of the hospital management, as there was no representation on that body, except from the Ladies' Association, which was a part of the hospital organisation.

Dr. ANDERSON spoke of the dangers of initial errors and said that as there appeared to be a medical re-organisation of the hospital in prospect it would be well to restart properly. He was of opinion that some of the motions did not go far enough; that there was a large amount of abuse, perhaps not very serious at present, which might easily extend itself. No medical staff was required for the hospital. A list of medical men ready to act if called upon in emergency was all that was required. It was essential that the local profession should be represented on the board of management by men not on the staff.

Mr. K. J. DOUGALL said that every local medical man ought to have an opportunity of attending his patients, to whatever part of the hospital they might be admitted. A rota of practitioners appointed for a month or so was all that was required.

Motions 2 to 5 inclusive were then passed *nemine contradicente*.

The SECRETARY then read the letter which had been sent out by the authorities of the Hampstead Hospital relative to the appointment of a consulting staff and quoting a letter from the executive of King Edward's Hospital Fund recommending the appointment of a consultant staff on the ground of the importance of the Hampstead General Hospital. The questions which the medical practitioners, addressed by the hospital, were asked to reply to included one in which a pure general practitioner staff was to be appointed as at present; a second as to an acting staff of consultant physicians and surgeons; and a third as to a mixed staff, composed partly of consultants and partly of general practitioners. The fourth asked for opinions as to the effect upon the popularity of the hospital likely to result from the change from general practitioner to consultant staff.

A motion was then proposed by Dr. SHARMAN and seconded by Mr. DOUGALL:—

> That the work of the hospital be carried on by local practitioners but in addition a limited list of surgeons, physicians, and specialists not belonging to the neighbourhood be kept for consulting purposes.

Dr. H. OPPENHEIMER moved as an amendment—

> That it is desirable both in the interest of the district and of the hospital itself that the Hampstead Hospital be carried on as a purely local institution, not as a large general hospital, and that therefore an acting staff of consultants is not in accordance with the spirit of its constitution.

This was seconded by Mr. R. HENSLOWE WELLINGTON.

Dr. COLLINGWOOD ANDREWS said that the hospital medical staff dissociated themselves entirely from the circular. They had had nothing whatsoever to say to it and were not consulted about it.

Mr. E. JESSOP said that the hospital staff had come there in an evidently friendly spirit, desirous of meeting the local medical profession not on the staff, and that it was desired to retain the present staff in office. There was no such thing as a pure consultant in London, they were merely rival practitioners, and he could not support the appointment of a staff of this nature.

Dr. SHARMAN said that it might be desirable to call in pure surgeons in the case of the performance of major operations at the hospital.

The CHAIRMAN remarked that this was done at the Willesden Cottage Hospital.

Dr. FORD ANDERSON mentioned the analogous case in respect to the Putney General Hospital as proposed. The local profession there were not desirous of a staff of consultants, but the terms of the deed of gift to that institution required the founding of a general hospital within a limited time or the money would go elsewhere. A compromise permitting a consulting staff to perform operations seemed likely to be the solution of the difficulty in the Putney case.

Dr. L. GLOVER pointed out that the Hampstead Hospital already had a staff of consulting physicians and surgeons. He said that the reason why there was so much dislike to the performance of surgery by general practitioners was that general practitioners had not formerly had the opportunity of performing many operations.

The CHAIRMAN inquired whether there was any limit to the operations performed in the Hampstead Hospital and whether the hospital rules required a consultation to be held prior to an operation. He pointed out that the absence of any restrictions in such matters might well account for the suggestion of the executive of the King's Fund for the substitution of an acting staff of consultants.

Dr. L. GLOVER replied that there were no such rules in force, either to limit the operations performed or as to their being preceded by a consultation. In practice eight out of ten of the operations were preceded by a consultation.

The amendment was then put to the meeting and carried with one dissentient. A rider was then moved by Mr. JESSOP:—

> That the work of the hospital be carried on by local practitioners, but in addition a limited list of physicians, surgeons, and specialists not belonging to the neighbourhood be appointed, who shall give their services in consultation as desired by the acting staff of the hospital.

But it was felt by the meeting that the rider introduced matters which it was desirable to avoid and the rider was withdrawn.

A protest was made by Mr. W. B. PEARSALL against the exclusion of Irish degrees from the medical qualifications required to be held by the staff prior to appointment.

On "the steps to be taken to carry into effect the objects of this conference," Dr. OPPENHEIMER moved that three or four members of the present meeting should be elected to coöperate with the local division of the British Medical Association and to take all steps deemed advisable, with power to add to their number. This was seconded by Dr. E. CLAUDE TAYLOR and carried *nemine contradicente*.

The following gentlemen were then nominated and agreed to: Dr. J. R. Whait, Dr. Walter Smith, Dr. Taylor, and Mr. Parsons.

The meeting terminated with a vote of thanks to the Chairman.

THE LONDON AND COUNTIES MEDICAL PROTECTION SOCIETY.

THE London and Counties Medical Protection Society held its annual general meeting, under the chairmanship of Dr. G. A. HERON, on May 4th, at 31, Craven-street, Strand, London, W.C.

The annual report gave many examples of the value to a member of the medical profession of belonging to a defence society, the following cases taken being good instances. A consulting physician received a demand from the solicitors of a patient for the return of all fees, subject to an action for damages for unskilful treatment. It seemed possible that the physician's diagnosis of an obscure ailment had been wrong but the complainant's solicitors were informed that the fees would not be returned and that the society would defend its member in any legal proceedings. No further action took place. Another member received a letter from the husband of a patient, accusing the member of causing his patient prolonged suffering by an alleged error in treatment, the treatment consisting in a bath of a pound of potassium sulphate to 30 gallons of water, when a troublesome dermatitis supervened. The member was advised how to reply and he was recommended to enforce payment of his fees, applying to the society for further assistance if occasion arose. No further assistance from the society was required. In another, case a claim was made against a medical man attending a hospital out-patient department for notifying a case as scarlet fever which was subsequently certified by the fever hospital not to have been scarlet fever. The claim was repudiated on the member's behalf and the complainant then instructed solicitors. The complainant's solicitors were written to and shown that there was no legal claim against the medical man even if he were mistaken, while there was much evidence in support of the view that the case was one of scarlet fever. The claim was not persisted in. A member of the society was unsuccessfully defended in an action brought against him by a club patient, claiming damages for libel and slander, the words complained of being written on a club certificate and uttered to persons officially connected with the club. The medical man relied on the communication being privileged but the jury awarded £150 damages against him, from which it would seem to follow that a practitioner should never, without the consent of the person examined (such consent being in writing or capable of legal proof), give his opinion of the nature of an ailment to anyone but the person examined. A member of the society was successfully defended against an accusation of adultery with a lady patient, a very accurate diary showing that misconduct could not have taken place on any of the occasions on which it was alleged, while the evidence was otherwise very weak. The jury unhesitatingly found the charge of adultery untrue. The judge said that there was not the slightest stain upon the medical man's character. All the expenses of the member's defence were borne by the society. The petitioner was ordered to pay a small periodical instalment towards defraying the costs.

The CHAIRMAN, in moving the adoption of the annual report and balance-sheet, referred to the satisfactory financial condition of the society. During the year 1905 446 new members were elected, 34 died, and 61 resigned their membership of the society because of retirement from practice, &c. The total membership at the end of the year was 3552; 226 members ceased to be in benefit owing to their subscriptions being in arrear. During the year 1905 the society's total income amounted to £2069 18*s.*, as compared with £1669 2*s.* 11*d.* during 1904. The total expenditure for the year amounted to £1786 3*s.* 8*d.*, leaving a surplus of income over expenditure amounting to £283 14*s.* 4*d.* At the end of the year the amount standing to the credit of the general account was £439 6*s.* 3*d.* and outstanding liabilities amounted to £137 0*s.* 9*d.* The reserve fund account stood at £2164 18*s.* 9*d.* and the total cash assets of the society stood at £2467 4*s.* 3*d.* In the course of his further remarks the chairman drew attention to the importance of the reserve fund and invited members to contribute towards it, and he suggested that when sending in their annual subscription the members should also remit some such sum as 10*s.* as a donation towards the reserve fund. He contended that this course was a most desirable one, because all must admit that the responsibilities undertaken by the society were very large, though the amount of the annual subscription was very small.

Dr. R. BOXALL seconded the motion, and this on being put to the meeting was carried unanimously.

After the transaction of some formal business the proceedings ended with cordial votes of thanks to the officers of the society.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH.

A QUARTERLY meeting of the College was held on May 1st, Dr. J. PLAYFAIR, the President, being in the chair. JOHN DIXON COMRIE, M.A., B.Sc., M.B., Ch.B. Edin., was introduced and took his seat as a Fellow of the College.

On a ballot the following candidates were admitted to the Membership of the College after examination: Augustus Kinsey-Morgan, M.D. Durh., M.R.C.S. Eng., Bournemouth; Edward Collett Hort, L.S.A., L R C.P. Irel., San Remo; William Augustine McEnery, L.R.C.P. Lond., M.R.C.S Eng., San Francisco; Alfred Nolan Fell, M.B., Ch.B. Edin., Edinburgh; Russell Gerald William Adams, L R.C.P. & S. Edin., Edinburgh; and J. William Keay, M.B., Ch.B. Edin., Edinburgh.

The REGISTRAR reported that since the last quarterly meeting 27 persons had obtained the Licence of the College by examination.

The CURATOR of the laboratory submitted his report for the last year. The report was adopted by the College.

Dr. James Andrew was re-elected as representative of the College on the Conjoint Committee of Management of the triple qualification.

It was intimated that Dr. A. R. Urquhart had been appointed Morison lecturer for the ensuing session.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 10th, 1828

TRIAL FOR DEFAMATION.—PARIS.

Roberts and Langeois, versus *Boyton*, *Morgan*, *Wilson*, *Chermside*, *and Maclaughlin*.

THIS cause, which was tried on the 10th of April, in the Tribunal de Premiere Instance, excited much interest amongst the faculty at Paris. The facts of the case, as we glean from the *Gazette des Tribunaux*, are as follows:—

An establishment for dispensing medicines, according to British prescriptions, was opened under the sanction of the Ambassador, Lord Granville, by Mr. Roberts, one of the plaintiffs; and having obtained the appointment of surgeon and apothecary to the Embassy, his affairs became very prosperous, the greater number of the English, resident in Paris, having recourse to Mr. Robert's establishment for their medicines. A M. Beral, a French apothecary, seeing the reputation which had been obtained by Mr. Roberts and his partner, M. Langeois, placed upon his door the title of London Dispensary, which, it seems, had previously been adopted by the plaintiffs. After a time it was found that the physicians to the Embassy recommended M. Beral's establishment in preference to Mr. Roberts'. This led to a publication of a letter in *Galignani's Messenge* , charging the physicians with having a direct pecuniary interest in sending their prescriptions to M. Beral. From this time there was open war between the parties, and in June, 1827, a letter, signed by thirteen *physicians*, was addressed to the British Ambassador, in which Mr. Roberts was styled a retail druggist, and was charged with having calumniated the *physicians*, by representing that they received a per-centage upon medicines This denunciation of Mr. Roberts being credited by Lord Granville, led to the withdrawal of his official employment, and, as a consequence, he experienced a considerable loss of business generally. These circumstances induced Mr. Roberts to commence an action, and he therefore selected five of the physicians, who had been most active in the proceedings against him. At a former sitting, the defendants had pleaded the incompetency of the tribunal appointed to try the cause, as the party was a foreigner; but this objection was overruled, on the ground of Mr. Roberts' partner, a plaintiff in the action, being a Frenchman.

M. Laterrade, the counsel for the plaintiffs, in opening the case, spoke to the foregoing effect, and further stated, that the injury sustained by Mr. Roberts was 10,000 francs a year; he therefore demanded 20,000 francs as damages.

M. Dupin, the counsel for the defendants, rested his defence principally upon the fact of the publication of an advertisement in *Galignani's Messenger*, and also an article in the *Hygéie* which stated, that the physicians, for the consideration of a certain annual sum, secured the supply of medicines to the apothecary.

M. Barthe made a very ingenious and humorous speech in reply to M. Dupin. He remarked that England certainly does possess many eminent physicians, but she is not so ungrateful as not to keep them at home by recompenses of every kind—reputation and fortune; and, whatever may be said to the contrary, he would contend, that persons do not *always* quit their country for the pure love of science; *he would appeal to Dr. Boyton if such were the case?* In England, said the learned counsel, diplomas, unless from Oxford or Cambridge, are but of little value; those obtained from Edinburgh are but very lightly estimated. One of Scotch or Irish origin may be had for forty guineas, upon the application being accompanied with a certificate of a physician of London, Cambridge, or Oxford, attesting that the party had attended medical lectures. A diploma from Scotland had been obtained for the horse of a nobleman, under ificate having previously the title of Mr. Goodfr been given that he was a gentleman of excellent disposition and great erudition. No matter as to the origin, continued M. Barthe; but where are the diplomas of the defendants? (Here M. Dupin held up *two* sheets of parchment, to each of which was affixed a seal.) M. Barthe then said, that these were the only diplomas possessed by the thirteen who signed the letter to Lord Granville. Upon application made at the office of the Minister of the Interior, he had learned that only one of the pretended physicians was authorised to practise the healing art in France, and this one possessed an Edinburgh diploma! Such are the *doctors*, said he, that Great Britain sends to France.

After a short deliberation, the Tribunal pronounced judgment, condemning the *Physicians* to pay 5,000 francs damages with costs, and to have twenty-five copies of the judgment posted up in the capital.

BRITISH MEDICAL BENEVOLENT FUND.

AT the April meeting of the committee of this Fund 13 applications were considered and the sum of £100 was voted in relief of those cases of which an abstract is appended. Two cases were passed over and two were postponed for further inquiry.

It was announced that the sum of £240 plus interest had been received from the trustees of the late Dr. John Grieve as the share allocated to the Fund out of the residue bequeathed by him to religious and benevolent societies. A donation of 50 guineas from the Edinburgh Harveian Society was also announced.

Mr. C. Stonham consented to act as honorary local secretary at the Westminster Hospital.

1. Widow, aged 42 years, of L.R.C.P., L.R.C.S. Edin., who practised in Cardiganshire. Quite unprovided for at husband's death and has had to sell practically all her furniture. Only one child able to help. Relieved once, £12. Recommended by Mr. E. Jones. Voted £12 in 12 monthly instalments.

2. Wife, aged 31 years, of M.R.C.S., L.R.C.P., who practised in Somersetshire, but is now confined in an asylum. Two children, aged nine and six. Has a little money in hand from the sale of the practice and will receive more during the next two years. Recommended by Mr. W. M. Beaumont (honorary local secretary). Voted £5 in one sum.

3. Widow, aged 59 years, of L.R.C.P. Edin., M.R.C.S. Eng., who practised in Yorkshire. Supported herself and assisted husband for 11 years by acting as housekeeper but now suffers from an incurable complaint. Slight help from children. Recommended by Dr. C. A. Lee. Voted £12 in 12 monthly instalments.

4. Daughters, aged 82 years and 67 years, of late M.R.C.S. who practised in Suffolk. Have supported themselves since father's death 24 years ago by keeping a boarding house but receipts have gradually decreased and now the furniture has been sold to defray the rent. Only income £15 a year. Recommended by Mr. T. J. Wayte. Voted £18 in 12 monthly instalments.

5. Widow, aged 59 years, of L.R.C.P., L.R.C.S. Edin., who practised in Northamptonshire. Income £28 a year from money left on trust; earns a little by needlework and receives slight help occasionally from a son. Health indifferent. Relieved five times, £50. Recommended by Dr. T. J. Walker. Voted £10 in two instalments.

6. M.D. St. And., M.R.C.S., L.S.A., aged 75 years. Used to have an excellent practice in London but it gradually dwindled owing to degeneration of the neighbourhood and competition. Only income a pension of £30 a year. Relieved twice, £24. Recommended by Mr. C. E. Moseley. Voted £12 in 12 monthly instalments.

7. Widow, aged 34 years, of L.R.C.P. Edin., who practised in Glamorganshire. No income. Two children, aged 11 and two and a half years. Endeavours to support herself by nursing but is unable to obtain constant work. Relieved twice, £10. Recommended by Dr. Joseph Bell (honorary local secretary). Voted £10 in two instalments.

8. Daughter, aged 65 years, of late M.R.C.S., L.S.A., who practised in Sussex. Income £20 a year from a charity. Health failing and very deaf. Relieved once, £6. Recommended by Dr. Frank Hinds. Voted £6 in 12 monthly instalments.

9. M.R.C.S., L.S.A., aged 66 years. Used to have an excellent practice in Staffordshire but has been quite incapacitated by paralysis and heart disease for five or six years, and is now dependent on a superannuation allowance from the guardians and such help as he can get from charities. Children unable to assist. Relieved four times, £50. Voted £15 in 12 instalments.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 6793 births and 4955 deaths were registered in the week ending May 5th. The annual rate of mortality in these towns, which had been equal to 17·3 and 16·7 per 1000 in the two preceding weeks, further declined last week to 16·3. The mean rate in these towns during the first five weeks of the current quarter was 16·9 per 1000, while it was 17·3 in London. The lowest death-rates during last week in the 76 towns were 7·2 in Hornsey, 7·3 in Willesden, 7·9 in King's Norton, and 8·4 in Leyton; the rates in the other towns ranged upwards to 21·2 in Hanley, 21·7 in Norwich and St. Helens, 22·2 in Oldham, and 27·1 in Liverpool. The 4955 deaths in the 76 towns showed a further decline of 125 from the numbers in the two previous weeks and included 463 which were referred to the principal infectious diseases, against 519 and 464 in the two preceding weeks; of these, 197 resulted from measles, 144 from whooping-cough, 42 from scarlet fever, 43 from diphtheria, 39 from diarrhœa, 18 from "fever" (principally enteric), and not one from small-pox. The deaths from these diseases were equal to an annual rate of 1·6 per 1000 in the 76 towns and to 1·5 in London. No death from any of these infectious diseases was registered last week in Brighton, Northampton, Norwich, Plymouth, Nottingham, Derby, or in ten other large towns, while they caused the highest death-rates in Burton-upon-Trent, Burnley, Walthamstow, Liverpool, and Yarmouth. The highest death-rates from measles occurred in Burnley, Walthamstow, Liverpool, and Yarmouth; and from whooping-cough in Coventry, Burton-upon-Trent, Merthyr Tydfil, and Bootle. Scarlet fever showed the greatest fatality in Leicester, diphtheria in Walthamstow, and diarrhœa in Wolverhampton. "Fever" caused five deaths in Birmingham. The number of small-pox cases remaining under treatment in the Metropolitan Asylums Hospitals at the end of last week were but three and no new case had been admitted during the week. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday, May 5th, was 2357, showing a further increase upon the numbers in the two previous weeks; 357 new cases were admitted during the week under notice, against 270, 288, and 314 in the three preceding weeks. The deaths referred in London to pneumonia and other diseases of the respiratory organs, which had been 399 and 361 in the two previous weeks, further declined last week to 309, but exceeded by 65 the corrected average for the corresponding week in the four preceding years, 1902-05. The causes of 55, or less than 1 per cent., of the deaths registered during the week in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Newcastle-upon-Tyne, Norwich, Nottingham, Bolton, and in 50 other large towns, whereas the proportion of uncertified deaths showed a considerable excess in Reading, Birmingham, Liverpool, Blackburn, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 17·6 and 18·4 per 1000 in the two preceding weeks, declined again to 18·0 in the week ending May 5th, but exceeded by 1·7 the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 10·8 and 15·6 in Paisley and Aberdeen to 20·6 in Dundee and 21·4 in Greenock. The 618 deaths in these eight towns included 22 which were referred to measles, 21 to whooping-cough, 13 to diarrhœa, eight to diphtheria, three to scarlet fever, three to "fever" (probably enteric), and not one to small-pox. In all, 70 deaths resulted from these principal infectious diseases during the week, against 53 and 62 in the two preceding weeks. These 70 deaths were equal to an annual rate of 2·0 per 1000, which exceeded by 0·4 the mean rate during the week from the same diseases in the 76 large English towns. The 22 fatal cases of measles in the Scotch towns showed a further increase upon recent weekly numbers and included 12 in Glasgow, five in Edinburgh, three in Dundee, and two in Leith. The 21 deaths from whooping-cough showed a decline of three from the number in the previous week, including 10 in Glasgow, four in Edinburgh, three in Aberdeen, and two in Dundee. Diarrhœa caused five deaths in Dundee, four in Glasgow, and two in Edinburgh. Six fatal cases of diphtheria and two of "fever" were returned in Glasgow and two of the three deaths from scarlet fever occurred in Edinburgh. The deaths referred in the eight towns to diseases of the respiratory organs, including pneumonia, which had been 170, 140, and 135 in the three preceding weeks, rose again last week to 138, and exceeded by six the number referred to these diseases in the corresponding week of last year. The causes of 25, or rather more than 4 per cent., of the deaths registered in the eight towns during the week were not certified, the proportion of uncertified deaths in the 76 English towns being rather less than 1 per cent.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·1 and 22·4 per 1000 in the two preceding weeks, rose again to 25·9 during the week ending May 5th. During the first five weeks of the current quarter the death-rate in the city averaged 24·2 per 1000, against 17·3 in London and 18·6 in Edinburgh. The 188 deaths of persons belonging to Dublin registered during the week under notice showed an increase of 25 upon the number returned in the previous week; they included only two which were referred to the principal infectious diseases, a fatal case each of whooping-cough and "fever." The two deaths from these principal infectious diseases were equal to an annual rate of 0·3 per 1000, the rate from these diseases in the same week being 1·5 in London and in 2·3 in Edinburgh. The 188 deaths in Dublin last week included 20 of infants under one year of age and 59 of persons aged upwards of 60 years; the deaths of infants showed a decline and those of elderly persons an increase upon the numbers returned in the previous week. Six inquest cases and three deaths from violence were registered; and 89, or 47 per cent., of the deaths were recorded in public institutions. The causes of five, or nearly 3 per cent., of the deaths were not certified either by a registered medical practitioner or by a coroner.

THE SERVICES.

Royal Navy Medical Service.

THE following appointment is notified:—Surgeon R. S. Osborne to the *Vivid*, additional for disposal.

Army Medical Staff.

Major Herbert J. M. Buist, D.S.O., R.A.M.C, to be a Deputy Assistant-Director-General, vice Major T. McCulloch, R.A.M.C., whose tenure of that appointment has expired (dated May 1st, 1906).

1st Life Guards.

Captain Alfred Crichton Lupton, from the Royal Army Medical Corps, to be Surgeon-Captain, vice B. Pares, promoted (dated May 5th, 1906).

Brevet.

Lieutenant-Colonel Francis Joseph Lambkin, R.A.M.C., to be Colonel, under the provisions of Articles 36 and 356 of the Royal Warrant of March 19th, 1906 (dated May 9th, 1906).

Royal Army Medical Corps.

Lieutenant Augustus S. Williams, from the Seconded List, to be Lieutenant (dated April 1st, 1906). Lieutenant-Colonel Octavius Todd to be Colonel, vice B. M. Blennerhassett, C.M.G., retired (dated April 4th, 1906).

Lieutenant W. C. Nimmo has assumed medical charge of women and children, Marlborough Lines, Aldershot.

Volunteer Corps.

Royal Garrison Artillery (Volunteers): 1st Aberdeenshire: The undermentioned officer resigns his commission: Surgeon-Captain H. M. W. Gray (dated May 5th, 1906). 3rd Durham: Henry Goudie to be Surgeon-Lieutenant (dated May 5th, 1906). 3rd Lancashire: Thomas Marshall Scott (late Lieutenant) to be Surgeon-Lieutenant (dated May 5th, 1906). 1st Shropshire and Staffordshire: Surgeon-Lieutenant-Colonel and Honorary Surgeon-Colonel E. Cureton resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated May 5th, 1906).

Royal Army Medical Corps (Volunteers).

Northern Command: Manchester Companies: Lieutenant G. Ashton to be Captain (dated May 5th, 1906).

On May 5th the London Companies of the Royal Army Medical Corps (Volunteers) paraded near the fire station in the Tooting Bec road and marched to Tooting Common where the wagons (four of which had come by road from headquarters) were unloaded, the men being divided into squads of two and four for the purpose of practising the erection of bell tents. Several of these tents were erected on a piece of ground previously measured out to represent a camp and a zest was given to the performance by the timing of each squad. At dusk the tents were struck and after having tea the corps marched back to Clapham-road. In the absence of the Colonel, Major J. Harper took command for the afternoon.

Deaths in the Services.

Colonel Daniel Frederick Bateman, I.M.S. (retired), on April 28th, at his residence, Woodcote, Ealing, aged 65 years. He entered the service as assistant surgeon in 1866; was promoted to surgeon in 1873; surgeon-major in 1878; surgeon-major, ranking as lieutenant-colonel, in 1886; brigade-surgeon in 1890; surgeon-colonel in 1893; and retired six years later. He served in the Burma Expedition, 1885–86 (medal with clasp).

Army Recruiting.

There was a debate in the House of Commons on May 2nd on Major Seely's motion concerning the question of recruiting for the present establishment of the regular army. But it led to no definite conclusion nor is any likely to be reached until Mr. Haldane has made up his mind and Parliament has agreed upon what is to constitute our future army system and organisation. The wastage entailed by our present system and the relative merits of long and short service were touched upon in the course of the debate, although not strictly pertinent to it. Mr. Arnold-Forster declared that a large proportion of that wastage was composed of young men who should never have been enlisted and that this had been largely reduced of late by the raising of the physical standard in the case of recruits. It is admittedly the case that at the present time we are not getting the requisite number and quality of young men for the army and the question comes, How are they to be obtained? Among other things some means will have to be devised for fitting soldiers to earn their own livelihood after leaving the army, and this, it is thought, may be done. Mr. Haldane, on behalf of the Government and in reply to many of the points that had been raised, stated about all that could be said in existing circumstances, but there is evidently much on which he has still to make up his mind. The subject is a very big and difficult one and we are glad to notice that he is patiently studying it with the aid of the best military experience available. As regards the relative merits of long and short army service, and even apart from the question of a reserve—in the case of India, for example—much turns on medical considerations.

Death of a well-known Army Nurse.

A correspondent writes: Memories of Spion Kop and other fierce struggles of the South African war will be recalled by the death, announced in a telegram received at the War Office, of Miss Lucie Todd, Q.A.I.M.N.S., acting matron of the Middelburg Hospital, Cape Colony. One of the first sisters to be sent out after President Kruger's declaration of war, Miss Todd arrived at the Mooi river base at the end of 1899, being attached to No. IV. General Hospital. Here she bore her full share of the heavy task of dealing with the wounded brought in from some of the bloodiest struggles of the campaign. Transferred to Elandsfontein and then to Pretoria she became at the end of the war acting matron successively of the hospitals at Mooi River, Pietermaritzburg, and Middelburg. Her health had begun to fail at Pietermaritzburg, but with the courage and devotion to duty which always characterised her she continued at work right up to the end of last year. Then she was forced to yield to the progress of a distressing illness, and she died at Middelburg on April 29th, in harness almost to the last. A highly skilled nurse, utterly unselfish in her dealings with others, Miss Todd was beloved by patients and fellow workers alike, and the army nursing service loses one who can ill be spared.

The Medical Examination of Petty Officers and other Ratings.

The *Army and Navy Gazette* states that instructions have been given that when medical examinations of men are being carried out due regard is to be paid to the desire to differentiate between petty officers and other ratings, and in view of the disciplinary question involved arrangements are to be made in order that petty officers may be treated with every consideration. When petty officers are attending with men the former are to be examined first and when required to strip each petty officer and man is to be examined separately.

THE HEALTH OF THE JAPANESE NAVY AND ARMY.

As will be seen from another column in THE LANCET Baron Takaki delivered the first two of a series of three lectures on the Preservation of Health among the *Personnel* of the Japanese Navy and Army at St. Thomas's Hospital on May 7th and 9th.

Colonel Kenneth Macleod, I.M.S. (retired), has been appointed honorary physician to the King.

Deputy-Inspector General of Hospitals and Fleets John Tyndall, R.N. (retired), has been awarded a Greenwich Hospital pension of £50 a year, vacant by the death of Deputy Inspector-General T. R. Warren.

The Torpoint (Cornwall) urban district council has received £5000 from the Admiralty towards the costs incurred by the council in promoting its Water Bill in Parliament.

Correspondence.

"Audi alteram partem."

ANTERIOR OR POSTERIOR GASTRO-JEJUNOSTOMY?

To the Editors of THE LANCET.

SIRS,—The letter from Mr. Herbert J. Paterson in THE LANCET of April 28th calls for a response from me.

The first point with which Mr. Paterson deals refers to the frequency with which the posterior no-loop operation has been performed. I had said in my previous letter that this method was the one which was now usually performed. Mr. Paterson replied that "in London, at any rate, the no-loop method is not yet that most commonly adopted." I answered that that did not meet my point and that "the operation of gastro-jejunostomy, if one may judge from published reports, is not so frequently performed in London as elsewhere." I suggested that Mr. Paterson should look further afield. How does Mr. Paterson reply to this? He writes, "*Possibly* we are behind the times, although I think that published reports are not a trustworthy indication of the volume of work done," &c. Leaving aside the question as to what other sources than published reports are generally accessible and as to why cases are "buried in the oblivion of hospital notes" when hospital reports are published, I would point out that a remark of this kind is not necessary to the argument and it appears to attach to my words a meaning which they did not possess and which I do not desire that they should possess. Mr. Paterson goes on to say further that he communicated with surgeons "all over the country" and he gathered from his inquiries that the no-loop operation is not commonly employed. Well, I must repeat my request for Mr. Paterson to look still further afield and to bring his inquiry up to date. Let him include the continent and America and I think he will find that I am right. I hope my search has been as careful as Mr. Paterson's; it has, I gather, been more extensive and more recent and my information goes to show that the posterior no-loop operation is now performed far more frequently than any other.

As regards Dr. Mumford's case, Mr. Paterson, as I pointed out, omitted to mention the one important fact—the congenital anomaly of the duodenum. The duodenum ended on the right side of the spinal column instead of the left. Owing to this abnormal fixation the stomach in its lateral contraction caused the anastomosis to be torn. Mr. Paterson says this abnormality "does not affect the conclusion to be drawn from the record." How can he possibly maintain that? But for the anomaly the disaster would never have occurred, and there would consequently have been no record from which to draw any conclusion. Mr. Paterson quotes Dr Mumford and then adds, "In other words, the no-loop operation is mechanically incorrect" Dr. Mumford's words cannot be made to bear this construction; moreover, Mr. Paterson is surely not entitled to argue, because of the failure of the no-loop method in one case where a gross congenital deformity existed, that the mechanics of the operation are incorrect when the anatomical conditions are normal. The mechanics of the operation in Dr. Mumford's case were wrong because, and solely because, of the duodenal deformity. There is not one scrap of evidence to show that under normal conditions the posterior no loop operation is ever mechanically incorrect; on the contrary, all the evidence that exists shows that it alone among all methods is the one which is free from mechanical complications and which, being completed, leaves the viscera in almost exactly their normal relations. (Mr. Paterson will, I know, be interested to hear that on Monday last I operated, with Dr. J. R. Lambert, upon a case precisely similar to Dr. Mumford's. I overcame the difficulty, not in the way I mentioned in my former letter, but by first suturing the upper part of the jejunum into the position the third and fourth parts of the duodenum normally occupy, and then performing the posterior "no-loop" operation. The patient is, so far, as well as possible.)

With regard next to internal strangulation. I have had three cases of hernia through the opening in the mesocolon into the lesser sac. The first patient died from the hernia on the tenth day. The other two patients developed the herniæ almost certainly within a few days or weeks of the operation, not, as Mr. Paterson said of one of them, after an interval of two years. *In none of these cases was the mesocolon sutured to the jejunum.* (Though I began my method of suture in August, 1903, I did not adopt it in every case, wishing, of course, to give it a trial first.) Since so suturing I have had no case of hernia, although the number of operations is much larger, and on all the occasions on which I have subsequently had the opportunity of seeing the anastomosis the aperture in the mesocolon has been securely closed. Mr. Paterson says he requires "further evidence that *in every case* the opening remains permanently closed." A modest demand surely? How we are to obtain this evidence without re-opening the abdomen of every patient who has been so operated upon I cannot conceive. The evidence I offer is that *in every case examined* the opening has remained permanently closed and that no case has had symptoms suggesting the occurrence of hernia, symptoms which, in the cases treated without mesocolic suture, developed very early after the operation. That is to say, that all the evidence which can possibly be available supports my contention. So far, then, as internal strangulation is concerned, it occurs after the anterior operation as a result of compression of the colon or from the passage of bowel over the proximal limb of the jejunum. It occurs after the posterior operation with a loop, either in the manner just mentioned or as a consequence of hernia into the lesser sac. After the posterior no-loop operation with the suture of the mesocolon to the jejunum it has never occurred. There is no jejunal limb over which intestine can pass and the suture closes the entrance to the lesser sac. The evidence here, then, is all in favour of the no-loop posterior operation.

So far as concerns jejunal ulcer, I do not disregard Mr. Paterson's contention that it is a more serious matter if it follows the posterior method than it is after the anterior method. That I should not dispute. But what I submit comes from a study of the cases recorded is that the condition is much less likely to occur, and, as a fact, has occurred less frequently, after the posterior method; though perhaps more serious it is undoubtedly much less frequent. Mr. Paterson's contention that the cases in which entero-anastomosis has been performed should be omitted from consideration is, I think, perfectly just. But even then there are almost three times as many cases after the anterior operation as there are after the posterior. And this I consider is a greater disproportion than should exist even if we limit the period of inquiry as Mr. Paterson does. There is a further point which escapes Mr. Paterson. In the earlier years of stomach surgery the anterior operation was performed more frequently than the posterior, but in the great majority of the early cases gastro-enterostomy was performed for cancer, and jejunal ulcer has never occurred, so far as I can discover, after malignant disease. If we consider then only the cases of simple ulcer and its complications (which alone furnish the examples of jejunal ulcer) it is not improbable that posterior has been performed even oftener than anterior gastro-enterostomy, for not a few of those surgeons who have practised both operations for years have reserved the anterior method almost exclusively for cases of carcinoma. When these considerations are remembered the so-frequent incidence of jejunal ulcer after the anterior method is very striking.

But there are, I think, other factors concerned not with the method of operation but with the conditions for which the operation is performed that are of more importance in the causation of jejunal ulcer than the position of the intestinal opening. The evidence shows, however, as I said previously, that so far as the details of the operation are concerned it is the low opening in the jejunum which disposes to ulcer; and I *submit that this is so, even when the* restrictions as to time, which Mr. Paterson desires, are made.

As regards regurgitant vomiting, Mr. Paterson and I agree that there is obstruction at the *anastomosis.* He *places* it at the efferent opening, saying, "I have witnessed a considerable number of necropsies on patients who have died from regurgitant vomiting and *in every instance* the waterlogging was clearly secondary to definite *mechanical obstruction at the* efferent opening." That may be, as Mr. Paterson claims, an "observed fact," though I am unaware of the nature of the evidence which supports it. Facts, as we know, depend sometimes for their existence, *and often for their interpretation,* upon the point of view of the observer. I cannot lay claim to the same kind of experience that Mr. Paterson has, but I have operated upon a certain number of these cases and the chief demonstrable condition has been a thick, overfull, proximal loop. That also is an observed fact which has been corroborated by several surgeons. *In these cases* an entero-anastomosis or Roux's operation relieved the obstructive vomiting.

Mr. Paterson asks, "Is there a particle of evidence that a healthy piece of intestine can become waterlogged *apart from mechanical obstruction?*" and adds "the whole of the small intestine is a series of loops. Do these loops ever become waterlogged *apart from the* conditions mentioned?" These questions are hardly relevant. We are not concerned *in this discussion* with loops of intestine, which are *free to* move where they will, but with a particular loop fixed naturally at one extremity—that is, at the duodeno jejunal flexure, and fixed unnaturally and in an abnormal position at *the other—that is, at the anastomosis.* I confess *I see no* resemblance between a loop both of whose ends are free and a loop both of whose ends are attached. Any arguments that might hold good relative to the one would be valueless *in the case of the other.* Mr. Paterson is straining a supposed analogy *too far.* If, *however,* he desires an *argument* by analogy, though most argument by analogy is necessarily imperfect, I would suggest for his consideration the conditions *which exist* when a loop of intestine, *otherwise* healthy, is fixed by an adhesion or by a diverticulum. Kinking may then result, and it is probable that distension may be active in bringing the obstruction about. Mr. Paterson attributes to me the belief in waterlogging as the "primary factor" and the "primary condition." I do not so consider *it and I did not use these words. The primary factor, of course, must be the fixation of the jejunum* to the stomach.

Not only is the gut fixed to the stomach, it is also materially weakened by the complete *division of its circular muscular fibres. Following upon* this is the occurrence of a kink or "buckle," due, as I consider, to the traction weight upon a part so weakened of a jejunal loop unable properly to empty *itself. That the obstruction (which, as I said* in my *first letter, is "the real cause"* of regurgitant vomiting) may affect the afferent as well as the efferent opening is shown by the fact that suspension of the *proximal loop by anchor sutures lessens* the probability of the occurrence of this complication. That the obstruction is due to the loop is shown by the fact that in the absence of a loop it *does not occur though the method* of *making* the anastomosis remains the same. If the *loop* plays no part in the causation of regurgitant vomiting and if the obstruction *is always at the efferent opening,* how comes it that the abolition of the *loop* in secondary operations, by its division and the performance of Roux's operation, relieves the vomiting though the anastomosis *itself remains untouched? And how is it that a loop* becomes waterlogged which *is free to empty* itself through an unobstructed afferent opening and that when vent is given to a waterlogged loop by *entero-anastomosis* the *obstructive vomiting* in *almost every case is at once relieved* though no change is made at either afferent or efferent opening?

Mr. Paterson, in answer to my query as to the existence of a surgeon who can bring forward any *large series* of cases of *the anterior operation which will* compare in results either immediate or remote with those obtained by the posterior method, quotes Dr. W. J. Mayo. He could not have chosen a better authority *for my purpose,* for, as Mr. Paterson says, Dr. Mayo with his enormous experience of both methods prefers the posterior. The sentence in Dr. Mayo's article which Mr. Paterson *italicises* as to the percentage of secondary operations being greater after the posterior operation than after the anterior suits my argument very well. *The* secondary operations were due, *almost* exclusively, to the *making of a loop in the posterior* operation, a method Dr. Mayo has now abandoned. Dr. Mayo's position is, indeed, very much the same as my own. I have used the anterior *operation, I have had good* results from it, *I* still use it, when I *must, I have* used the posterior *operation* with the loop, and I have had to perform secondary operations, but for the many reasons I have given I now perform, *and very decidedly prefer, the posterior no-loop* method. Mr. Paterson again *expresses his satisfaction* with the anterior method. I cannot, of course, cavil at that; on the contrary, indeed, I admire Mr. Paterson's zeal and persistence *and his touching* faith all the more when I remember that in the little he told us of his own experience he had to chronicle in his lectures the death of two of his patients from regurgitant vomiting. *But he has not,* as I *said before, told us* what, *if* any, his experience of the posterior method is. If he will give that method a trial he will, *I* anticipate, come to the conclusion, as so many of us have done, that though the anterior method is good the posterior is rather better, and the posterior *no-loop* is best of all.

Mr. Paterson writes: "As yet I have not found any conclusive evidence *to show that the results, either immediate* or remote, are better after the posterior than after the anterior operation. If such evidence be forthcoming Mr. Moynihan need have no fear but that I shall act in accordance with it."

Mr. Paterson's needs in the matter of evidence are difficult to estimate. As I have shown, in one matter he bases a deliberate statement of opinion upon the evidence afforded by one case when the circumstances *were abnormal* and *unprecedented; in another he does* not accept the evidence afforded by every available case, as he wishes for an impossible verification of that evidence "in every case." Nevertheless, I will endeavour *to* indicate where the evidence upon *this subject may be* found. What, to begin with, is the evidence that Mr. Paterson has already studied? He has told us in his lectures that he has "collected 247 cases of *operation* from British surgical *literature of the last 20 years,"* and has obtained the *after-history of* 116 of these cases. Of these 116 cases there are 32 of my own, all but *one* being examples of posterior *gastro-enterostomy.* Of the remaining 84 cases it is not stated what was the proportion of anterior and posterior operations. Upon this evidence and upon his own experience, which, *I suspect* is confined to the anterior operation only, Mr. Paterson has formed his judgment. Well, I can offer Mr. Paterson out of my own experience—indeed, I have already sent *to him—reports of a far larger number of cases* than this. So far as immediate results are concerned my mortality, excluding the acute cases of perforation and hæmorrhage, is less than 1 per cent., and I have now had *125 cases in succession* without a death. So *far as* the remote results are concerned, Mr. Paterson has the material upon which to form his own opinion. He very properly, in estimating the *remote results, says* of his own investigations, "only cases which were operated upon *more than two years* ago are included." In the report I have sent to Mr. Paterson he will find *that up to the end of April,* 1904, there are 124 cases of mine whose history was brought up to date. I shall be *glad for* Mr. *Paterson to make direct inquiry* about them or about any of the *later cases. Further,* I would venture to *suggest* to Mr. Paterson to include in his search for evidence—evidence which already exists—what the surgeons *whose names* I gave *him in my* last *letter* and the several surgeons who spoke at the recent meeting of the International Society of Surgery have to say. The result of his research will be, I venture to predict, that he will find that, with *extremely few exceptions,* those surgeons who *are* doing, and have done, the largest work in this field have come to the conclusion, after trying all methods—*anterior,* posterior, with *or* without a loop, and Roux's *operation—that the* evidence *is in favour of* the posterior method, and he will further find that it is the no-loop *operation* that is the almost universal choice. If Mr. Paterson *will take the opinion or* watch the practice of these *surgeons,* and, above all, if he will give to the posterior *no-loop* operation a trial equal to that he has given the anterior method, he will then be in a better position than he now is to express an *opinion* upon the relative merits of the *two methods.* I shall be interested to hear what conclusion he then forms. Mr. Paterson and many others who write upon the subject speak of the anterior operation as being much "simpler" than the posterior and this simplicity is held to be an advantage. I can assure Mr. Paterson that the posterior operation can be made every whit as simple as the anterior. If Mr. Paterson will accept the invitation I formerly gave him, and now cordially repeat, to "come and see," I shall not be without the hope of convincing him that the posterior no-loop operation can be made as easy as it is possible for a gastro-enterostomy operation to be, and that his statement that "the anterior is admittedly the simpler and less complicated procedure" can be successfully refuted.

I hope it will not be thought that, though my views upon the matters we have discussed are diametrically opposed to those held by Mr. Paterson, I wish to be chary in my estimate of the great value of his lectures. They are, I think, of quite unusual excellence.

I am, Sirs, yours faithfully,

Leeds, April 29th, 1906. B. G. A. MOYNIHAN.

To the Editors of THE LANCET.

SIRS,—In the course of the controversy in the correspondence columns of THE LANCET I have come by degrees to the conclusion that a piece of epoch marking work in this department of surgery is in danger of losing its identity. And to-day I have read a statement made by Dr W. J Mayo in a communication to the *Annals of Surgery*, November, 1905, which I quote: "In the summer of 1903 Mr. Moynihan demonstrated to us the method he was using with the clamps and which goes by the name of the Moynihan operation," &c.

On Oct. 19th, 1900, my colleague, Mr. H. Littlewood, made a communication to the Leeds and West Riding Medico-Chirurgical Society upon a method of performing intestinal suture which he had been led to devise and carry out in consequence of the spontaneous closure of the gastro-enterostomy opening in two cases not in his own practice. I refer your readers to THE LANCET of June 29th, 1901, p. 1817, in which Mr. Littlewood describes the operation he had invented, which is essentially—indeed, with many of us identically—the same operation that is performed to day, that is, by the aid of rubber sheathed Doyen's forceps and with the excision of an ellipse of mucous membrane from each viscus.

There are two variant details the value of which is variously estimated, and it may be that Mr. Moynihan attaches so much importance to them and has practised them successfully for so long that he has come to regard them as the core and origin of the whole procedure. I refer to (1) the first line of suture, and (2) the question of "loop or no loop." Mr. Littlewood incised the serous and muscular coats and stripped them up a little in the submucous layer before he sutured them. Mr. Moynihan places his first line of suture through the outer coats before incising them. This is obviously a quite minor point, and some surgeons use either method indifferently. As a matter of fact, Mr. Littlewood now completes his incisions before he puts in any sutures at all, and he claims as the resulting advantage that there is no risk of soiling any suture already *in situ*.

Mr. Moynihan attaches great importance to the establishment of the jejunal opening as high as possible. It may even be that he has come to regard this as the essential feature of the operation, but if so I would point out that this is not what Dr. Mayo refers to as the Moynihan operation; and that the method of intestinal anastomosis by means of Doyen's clamps and the excision of ovals of the mucosa, if it is to be known by the name of its author, should be called the Littlewood operation. The omission to put this matter of authorship and precedence in a clear light is probably, as it may so easily be, a mere inadvertence on Mr. Moynihan's part, and Mr. Littlewood's reticence has led me to recall the sequence of events as we who witnessed these developments so well remember it. In Robson's and Moynihan's book, published ten months *after* Mr. Littlewood's original paper, no mention is made of clamps.

My reason for asking leave to publish these remarks in your columns is to afford Mr. Moynihan the opportunity, of which I am sure he will be only too willing to avail himself, of publicly stating how far Dr. Mayo and those who accept his statement are in error in withholding from Mr. Littlewood the credit of the pioneer work in this important advance in intestinal surgery. Whether the operation is anterior or posterior; whether the outer coats should be incised before suture or sutured before incision; whether a jejunal loop is undesirable or not—these points, even the last of them, are, so far as concerns the principle, the method, the technique, of the operation, of lesser importance; the essential features are: (1) the use of rubber-sheathed Doyen's clamps, with the fourfold object of steadying the parts in apposition during suture, preventing puckering and contraction from too tight stitching, preventing the escape of intestinal contents, and controlling hæmorrhage; and (2) the excision of elliptical portions of mucous membrane from each organ, so as to produce and maintain a free oval opening and to prevent the healing of the cut edges across the gap.

By far the worse of my own two cases of circulus vitiosus was after a posterior operation in which I took special pains to make the anastomosis as high as possible, short of producing actual tension at the time. The absence of any loop made the later treatment of this case a matter of the greatest possible difficulty and anxiety. In my other case, an anterior operation, the condition was easily converted into a Roux's operation, but, although not a very early convert, I have for some time been a convinced believer in the advantages of the posterior operation in all cases—a very large majority—where it is practicable. It would be very interesting if Dr. Mayo would formally restate what he regards as the important, the essential, points of the operation.

I am, Sirs, yours faithfully,

Leeds, May 2nd, 1906 EDWARD WARD.

CASEIN AND CASEINOGEN.

To the Editors of THE LANCET.

SIRS,—My attention has been called to a letter from Mr. H. Droop Richmond in THE LANCET of April 28th, in which he repeats the protest contained in his book against the use of the words caseinogen and casein in the sense in which they are employed in my writings on the subject. Proteid nomenclature in general is in such a confused condition just now that a joint committee of the Chemical and Physiological Societies has been appointed to attempt to reduce the chaos to order. Among the recommendations of this committee I find the following. "They strongly urge the continued use of the words caseinogen and casein in the sense now employed in the majority of English text-books." It would be most desirable for analytical chemists to fall into line also. The words are most helpful to teachers and students and have the recommendation of being rational.

The word casein is derived from the Latin word *caseus*, which means cheese. Cheese is the result of the action of rennet and calcium salts on the principal proteid of milk, and so it is right to apply the term casein to the curdled product and not to the original proteid upon which the rennet acts. The original proteid begets the casein; it is the mother substance of the cheese and so is rightly named caseinogen. The termination *gen* is derived from the Latin verb *genero* (I beget or produce). Caseinogen is therefore not a hybrid as Mr. Richmond says. Does Mr. Richmond also propose that we should drop the word fibrinogen and call it fibrin? Such a proposal would be quite on all fours with his suggestion that we should resort to the antique terminology he has not yet abandoned and call caseinogen casein. His statement that Dr. Gustav Mann has confused the two words is not an argument in his favour. The so-called confusion is due to an obvious press error which will be corrected in future editions of Dr. Mann's book.

I may add in conclusion that the word caseinogenate which Mr. Richmond fears may be introduced is already largely employed in physiological literature and bids fair to become as firmly rooted as caseinogen. Surely a chemist is the last person to object to words on account of their length.

I am, Sirs, yours faithfully,

King's College, London, May 4th, 1906. W. D HALLIBURTON.

THE TRANSMISSION OF LEPROSY.

To the Editors of THE LANCET.

SIRS,—You will be glad to learn that Dr. W. J. Goodhue, medical superintendent of the Molokai Leper Settlement, has after several years' work there been able to demonstrate the bacillus lepræ (Hansen) in the mosquito (Culex pungens) and in the bed bug (Cimex lectularia). I will quote from my brother's official report to the Hawaiian Board of Health:—

> "We have since been sectioning mosquitoes taken from various leper houses, but until last June [letter dated Feb. 10th, 1906] without any apparent success. At that time it appeared that we had isolated

intestinal opening. *The evidence shows, however, as I said* previously, that so far as the details of the operation are concerned it is the low opening in the jejunum which dis*poses to ulcer; and I submit* that this is so, even when the restrictions as to time, which Mr. *Paterson desires,* are made.

As regards regurgitant vomiting, Mr. Paterson and I agree that *there is obstruction at the anastomosis. He* places it at the efferent *opening, saying,* "I have witnessed a considerable number of necropsies on patients who have died from regurgitant vomiting and in every instance the waterlogging was clearly secondary to *definite mechanical obstruction* at the efferent opening." That may be, as Mr. Paterson claims, an "observed fact," though I am unaware of the nature of the *evidence which supports it. Facts,* as we know, depend sometimes for their existence, and often for their interpretation, upon the point of view of the observer. I cannot lay claim to the same kind of experience that Mr. Paterson has, but I *have operated upon a certain* number of these cases and the chief demonstrable condition has been a thick, overfull, proximal loop. That also is an observed fact which has *been corroborated* by several surgeons. In these cases an entero-anastomosis or Roux's *operation* relieved the *obstructive* vomiting.

Mr. Paterson asks, "Is there a particle of evidence that a healthy piece of intestine can become waterlogged apart from mechanical obstruction?" and *adds* "*the whole of the* small intestine is a series of loops. Do these loops ever become waterlogged apart from the conditions mentioned?" *These questions are hardly relevant.* We are not *concerned* in this discussion with loops of intestine, which are free to move where they will, but with a particular loop fixed naturally at one extremity—that is, at *the* duodeno jejunal flexure, and fixed unnaturally and in an abnormal *position* at the other—that is, at the anastomosis. I confess I see no resemblance between a loop both of whose ends are free and *a loop both of whose ends are attached. Any arguments* that might hold good relative to the one would be valueless in the case of the other. Mr. Paterson is straining a supposed *analogy too far. If, however,* he desires an argument by analogy, though *most argument* by analogy is necessarily imperfect, I would suggest for his consideration the conditions which exist when a loop of intestine, otherwise healthy, *is fixed by an adhesion or by a diverticulum.* Kinking *may* then result, and it is probable that distension may be active in bringing the obstruction about. Mr. Paterson attributes to me the belief in waterlogging as the "*primary factor*" *and the* "*primary condition.*" I do not so consider it and I did not use these words. The primary factor, of course, must be the fixation of the jejunum to the stomach.

Not only is the gut fixed to the stomach, it is also materially weakened *by the complete* division of its circular muscular fibres. Following *upon this is the occurrence of a kink or* "*buckle,*" *due,* as I consider, to the traction weight upon a part so weakened of a jejunal loop unable properly to empty itself. That the obstruction (which, as I said in my first *letter,* is "*the real cause*" of *regurgitant* vomiting) may affect the afferent as well as the efferent opening is shown by the fact that suspension of the proximal loop by anchor sutures *lessens the probability of the* occurrence of this complication. That the obstruction is due to the loop is shown by the fact that in the absence of a loop it does not occur though *the method of* making the *anastomosis remains* the same. If the loop plays no part in the causation of regurgitant vomiting and if the obstruction is always at the efferent opening, how comes it that the abolition of the *loop in secondary* operations, by *its division* and the performance of Roux's operation, relieves the vomiting though the anastomosis itself remains untouched? And how is it that a loop *becomes* waterlogged *which is free to empty* itself through an *unobstructed* afferent opening and that when vent is given to a waterlogged loop by entero-anastomosis the obstructive vomiting *in almost every case is at once* relieved though no change is made at either afferent or efferent opening?

Mr. Paterson, in answer to my query as to the existence of a surgeon who can *bring forward* any large series of cases of the anterior operation which will compare in results either immediate or remote with those *obtained by the* posterior method, quotes *Dr. W. J. Mayo.* He could not have chosen *a better* authority for my purpose, for, as Mr. Paterson says, Dr. Mayo with his enormous experience of both methods prefers the posterior. The sentence in *Dr.* Mayo's article which Mr. *Paterson* italicises as to the percentage of *secondary operations being* greater after the posterior operation than after the anterior suits my argument very well. The secondary operations were due, almost exclusively, *to the* making of a loop in the posterior operation, a method Dr. Mayo has now abandoned. Dr. Mayo's position is, indeed, very much the same as my own. I have used the anterior operation, I have had good results from it, I still use it, when I *must,* I have used the posterior operation with the loop, and I have had to perform secondary operations, but for the many reasons I have given I *now* perform, and very decidedly prefer, the posterior no-loop method. Mr. Paterson *again* expresses *his* satisfaction with the anterior method. I cannot, of course, cavil at that; on the contrary, indeed, I admire Mr. Paterson's zeal and persistence and his touching faith all the more when I remember that in the little he told us of his own experience he had to chronicle in his lectures the death of two of his patients from regurgitant vomiting. But he has not, as I said before, told us what, if any, his *experience of the posterior* method is. *If he* will give that method a trial he will, I anticipate, come to the conclusion, as so many of us have done, that though the *anterior method is good* the posterior is rather better, and the posterior no-loop is best of all.

Mr. Paterson writes: "As yet I have not found any conclusive evidence to show that the results, either immediate or *remote,* are better *after the* posterior *than after* the anterior operation. If such evidence be forthcoming Mr. Moynihan need have no fear but that I shall act in *accordance with it.*"

Mr. Paterson's needs in the matter of evidence are difficult to estimate. As I have shown, in one matter he bases a *deliberate* statement of opinion upon *the* evidence afforded by one case when the circumstances were abnormal and unprecedented; in another he does not accept the evidence afforded by every available case, *as he wishes for an impossible verification* of that evidence "in every case." Nevertheless, I will endeavour to indicate where the evidence upon this subject may be found. *What, to begin with,* is the evidence that Mr. Paterson has already studied? He has told us in his lectures that he has "collected 247 cases of operation from British surgical literature of the last 20 years," *and has obtained* the after-history of 116 of these cases. Of these 116 cases there are 32 of my own, all but one being examples of posterior gastro-enterostomy. Of *the* remaining 84 cases it is not *stated what was the proportion* of *anterior and posterior* operations. Upon this evidence and upon his own experience, which, I suspect is confined to the anterior operation only, Mr. *Paterson* has formed his judgment. Well, I can offer Mr. Paterson *out of* my own experience—indeed, I have already sent to him—reports of a far larger number of cases than this. *So far as* immediate results are *concerned* my mortality, excluding the acute cases of perforation and hæmorrhage, is less than 1 per *cent.,* and I have now had 125 cases in *succession* without a death. So far as *the remote results* are concerned, Mr. Paterson has the material upon which to form his own opinion. He very properly, in estimating the remote results, says of his own investigations, "*only cases* which were operated upon more than two years ago are included." In the report I have sent to Mr. Paterson he will find that up to the end of April, 1904, there are 124 *cases of mine* whose *history was brought up* to date. I shall be glad for Mr. Paterson to make direct inquiry about them or about any of the later cases. Further, I would venture to suggest to Mr. *Paterson to include in his search* for evidence—evidence which already exists—what the surgeons whose names I gave him in my last letter and the several surgeons who spoke at the *recent* meeting of the International Society of Surgery have to say. The result of his research will be, I venture to predict, that he will find that, with *extremely* few exceptions, those surgeons *who are* doing, and *have* done, the largest work in this field have come to the conclusion, *after* trying all methods—anterior, posterior, *with or* without a loop, and Roux's *operation*—that the evidence is in favour of the posterior method, and he will further find that it is the *no-loop* operation that is the *almost* universal choice. If *Mr. Paterson* will take the opinion or watch the practice of these surgeons, and, above all, if he will give to the posterior no-loop operation a trial *equal to* that he has given the *anterior* method, he will then be in a better position than he now is to express an opinion upon the relative merits of the two methods. *I shall be interested*

24 hours. On the following day there was slight eye pain, with considerable reduction of the visual acuity. The pupils were of medium size and the reaction was normal. I advised her to remain in a darkened room, to have the eyes gently massaged, and to take a hot bath. I gave internally bromide of ammonium. She wore tinted glasses for some days and is now quite recovered.

The condition produced by exposure to excessive light is sometimes spoken of as blindness of the retina, anæsthesia of the retina, and neurasthenic asthenopia. "Retinal electrocution" is the term Darier uses when writing of the cerebral and retinal shocks produced by the passage of an electric current through the upper part of the body and the head. This suggests to me the term "retinal-cinematocution" for the condition produced by the intense flashes of white light. Those who have witnessed these living-picture displays must have experienced that peculiar "tiredness" of the eyes caused by exhaustion of the retina, and how gratifying it was to close the eyelids and thus relieve the strain. Until some improvement takes place in the mode of exhibiting these pictures and in rendering less intense the light the public should be warned of the danger and advised to wear tinted glasses when looking at them, and each display should not exceed one minute.

I am, Sirs, yours faithfully,

Dublin, May 5th, 1906. EDWARD MAGENNIS, M.D. R.U.I.

PASTEURISED MILK AND INFANT FEEDING.

To the Editors of THE LANCET.

SIRS,—In calling attention to a prevalent and growing evil the letter of Dr. G. A. Sutherland in THE LANCET of May 5th, p. 1280, is a highly important and valuable one. As far as the evidence of my cases quoted by him is concerned, he might have materially strengthened his position by mentioning the chief feature that was the main point of interest in each. The "extraordinary course" referred to in my paper was not the mere delay in the resolution of a subperiosteal clot but the formation of new bone in the detached periosteum in each of three consecutive cases of scurvy inadvertently fed on pasteurised milk. In one case where the change of milk instituted by the dairy company was not discovered and the infant died the newly formed periosteal bone was of remarkable extent, being thicker in places than the femur it surrounded. In the succeeding two, whilst on pasteurised milk, a thin layer of bone formed in the periosteum detached from the femur—a condition that was verified by skiagrams taken by Dr. G. H. Graham. On a change being made from pasteurised to fresh milk the new bone formation ceased in each and in the course of time that already formed was slowly absorbed. These three cases would seem apt illustrations of the dangers of pasteurised milk pointed out by Dr. Sutherland in his timely letter. I am, Sirs, yours faithfully,

London, May 7th, 1906. J. A. COUTTS.

PRIMARY CARIES OF THE MASTOID PROCESS AS A CAUSE OF MASTOID ABSCESS IN YOUNG CHILDREN.

To the Editors of THE LANCET.

SIRS,—I should like to supplement Mr. L. P. Gamgee's cases of caries of the mastoid (recorded in THE LANCET of May 5th, p. 1237) with two cases which have been recently under my care. My cases have many points in common with his, but not all. The first was that of a child, 15 months old, with a swelling behind the ear of six weeks' duration. The child never had "running ear" or any of the symptoms of pain usually associated with mastoid abscess. There was a large fluctuating swelling behind the right ear pushing it forwards. I incised this down to the bone, and after mopping away blood and pus found a sinus leading into the antrum. This I enlarged sufficiently to allow the antrum to be easily packed with gauze. I removed very little bone and only very gently used a small curette to scrape out the antrum. It was packed daily, and in five weeks the cavity was completely closed. I had an opportunity of examining the membrana tympani afterwards and found that it differed in no respect from the other side.

The second case was that of a boy, aged nine years. He began with a swelling behind the left ear, which continued to increase in size under assiduous poulticing. I saw him after six weeks of this treatment and found a large fluctuating abscess, extending over the mastoid and beneath the temporal fascia, pushing the ear markedly forwards. This boy never had earache or otorrhœa and during all the time he was under my care his temperature never ranged above 99° F. I incised as in the former case and found a sinus which from its high and anterior situation I thought opened into the attic, not into the antrum proper. This I enlarged and packed the cavity daily. At the end of seven weeks it was completely healed. The membrane at the present time is perfectly normal in appearance and the boy can hear a watch distinctly at 38 inches.

These two cases agree with Mr. Gamgee's in the following points: (1) absence of constitutional disturbance; (2) there never was otorrhœa; and (3) the swelling came on gradually with an absence of pain. They differ in the following: (1) the ear was pushed markedly forwards in both; and (2) there was hardly any destruction of bone. There was no caries except at the margin of the sinus itself.

I am, Sirs, yours faithfully,

Leeds, May 7th, 1906. J. STEWART.

APPENDICITIS AND PERFORATED DUODENAL ULCER.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 5th, p. 1262, in "Annotations," under the heading of "Appendicitis and Perforated Duodenal Ulcer," you say: "No case appears to have been recorded of the association of inflammation of the appendix with duodenal ulcer." May I venture to call your attention to the fact that in THE LANCET of Nov. 2nd, 1901, p. 1194, I published notes of a case of appendix abscess that I opened and that died from a perforated ulcer of the second part of the duodenum 11 days later. I also in the same note gave details of two other cases of perforated duodenal ulcer associated with a septic condition of the peritoneal cavity.

I am, Sirs, yours faithfully,

Leicester, May 7th, 1906. F. BOLTON CARTER.

THE EPIDEMIOLOGICAL SOCIETY.

To the Editors of THE LANCET.

SIRS,—I should be much obliged if you would kindly permit me to make a few corrections in the account published in THE LANCET of May 5th of a paper which I had the honour of reading before the Epidemiological Society on April 20th last on the subject of the meningococcus. In the first place, Elser of New York cultivated the meningococcus from the blood in 24 per cent. of the cases of cerebro-spinal fever which he examined, *not* in 7 per cent. as stated. "Colonies in broth" should read "colonies on nasgar," and "acetic" agar should read "ascitic" agar. Instead of saying that both the meningococcus and micrococcus catarrhalis were liable, as indeed were all micrococci, to occur as staphylococci and streptococci, I stated that they *were all* apt to occur as diplococci. Lastly, the disinfection experiments quoted were made against saliva, not against cultures of the meningococcus.

I fear that I myself am in great part to blame for these "terminological inexactitudes," because I failed to bring an abstract with me on the occasion in question.

I am, Sirs, yours faithfully,

Blackheath, May 8th, 1906. M. H. GORDON.

THE NOTIFICATION OF PULMONARY TUBERCULOSIS.—The Barnstaple (Devon) rural district council recently forwarded a resolution to the Local Government Board urging that pulmonary tuberculosis should be included amongst the list of notifiable diseases. At the meeting of the council held on May 4th a letter was read from the Local Government Board stating that pulmonary tuberculosis was not a disease to which compulsory notification could with advantage be applied, but as many authorities had made arrangements with local medical practitioners for the voluntary notification of this disease the Barnstaple rural district council could follow this course without the sanction of the Local Government Board and pay a reasonable fee for such notification.

> bacilli in these series of experiments, but *owing to the technique* employed it was impossible to positively confirm this ..... This method of research was then *abandoned.* . ... *Mosquitoes* were caught at random in leper houses, being captured with a net or sterile test-tube, and the same *subjected to a vapour of ether* when the mosquito became unconscious and was easily caught up with sterile *forceps* and *placed under the dissecting microscope.* ...... After repeated failures and the constant re-examination of fresh *specimens success has come as far as demonstrating* the bacillus *lepræ in* the female mosquito (Culex pungens). ...... Feb. 20th. Since writing you last I have discovered the bacillus lepræ in the bed bug. I believe that the cimex is more of a factor in the spread of leprosy *among the natives than the gnat*, for the *following* reasons, viz., the bed bug's *invasion* is noiseless and insidious, made during deep sleep of the victim, and secondly, the beds and bedding used in a leper family, *whether* the leper is dead or segregated, are reoccupied by clean persons without adequate disinfection and cleaning.

The bacilli have been found in numbers in the ovaries and Malpighian tubules of the mosquito. Full reports of the work with microphotographs and slides, &c., will be given publicity in May.—I am, Sirs, yours faithfully,

E. S. GOODHUE.
Government Physician.

Laaloa Holualoa, Hawaii, T.H., April 9th, 1905.

THE TREATMENT OF TEMPORARY FORMS OF MENTAL DISORDER.

To the Editors of THE LANCET.

SIRS,—I have read with very great pleasure your remarks in THE LANCET of April 28th, p. 1190, on the treatment of curable cases of insanity. As one who has *repeatedly* advocated the treatment of temporary cases of mental disorder *outside* a lunatic asylum it is gratifying to find that you are in sympathy with this solution of a very difficult problem. In THE LANCET of June 14th, 1902, p. 1681, I published a paper on the Relation of Mental Symptoms to Bodily Disease, and there I strongly advocated the provision in all large centres of the community of observation hospitals into which temporary forms of acute mental disease, such as acute alcoholic insanity, puerperal mania, acute toxic delirium, and acute transient forms of mania or melancholia, might be admitted and treated by skilled physicians for a period of six weeks. If at the end of that time the patient showed no disposition to recover then he should be certified for removal to a lunatic asylum. Whilst not in any way reflecting on the equipment, control, and scientific treatment of the present lunatic asylums there can be no doubt that a very large number of cases of mental disorder are certified as lunatics and sent to asylums when in reality they ought to be treated in the most modern and scientific way in a mental hospital. This might either be attached to the present general hospitals where they would have the advantage of a trained staff of physicians and students, or a mental hospital might be provided in large centres so as to filter out the quickly recoverable cases from the ordinary lunatics. My object in advocating this method is to obviate the necessity under the present Lunacy Act of certifying as lunatics a large number of cases of temporary mental disorder which are always occurring in large towns and cities. The stigma of lunacy ought not to be attached to these people, more especially to those suffering from puerperal insanity, but at the present time there is no place in which these people can be treated excepting the workhouse or the workhouse infirmary unless they are certified as insane and treated in the lunatic asylums.

I am, Sirs, yours faithfully,

NATHAN RAW.

Liverpool, May 2nd, 1906.

TO MEDICAL OFFICERS OF HEALTH: A SUGGESTION.

To the Editors of THE LANCET.

SIRS,—For many years I have been greatly concerned in my midwifery practice with the heterogeneous class of nurses that I, in common with most medical men, come across, from the comfort of the well-trained to the continual anxiety caused by the mighty host of the ignorant and the unclean. A not uncommon state of things on entering a lying-in room is to meet the nurse with dirty hands and dirtier nails, perhaps after scrubbing the floor, and placing some foul garment to the vulva of the patient who is lying on, and surrounded by, such soft goods as old curtains, carpets, and, in fact, almost every kind of filthy stuff short of the door-mat. I have for many years endeavoured to teach these women habits of strict cleanliness. I never allow them to wash the genitals and when a napkin has to be changed I insist on their going through a process of first washing thoroughly their hands and nails, then soaking them in bichloride, and, finally, wringing a cloth out of a warm solution of bichloride before placing it next the patient, a dry one, baked, straight from the oven, being placed outside. The constant worry and anxiety in thus dealing with and teaching these women is intolerable and it struck me recently what boundless good—and at a very small cost—could be accomplished if the medical officers of health were to induce their parochial councils to get someone to give free, simple lectures on the essentials of monthly nursing to these folk, say once a week or even once a month, of an hour or two, and let certificates be given to the proficient.

Apart from the danger of septic trouble to the mother, the life of the infant is jeopardised by improper feeding and his lungs are impregnated at the very commencement of his life by foul air, the bedclothes almost invariably covering his head "that he may not catch cold."

If these women, by the method I suggest—simple, inexpensive, and feasible—are raised to a higher level, and if we medical men, one and all, adopt, as regards our own hands and nails and instruments and the person of our patient, prophylaxis as the most exacting can wish for, puerperal fever, as far as the profession is concerned, will become a rare disease. I am, Sirs, yours faithfully,

S. CONSTABLE.

Endymion-road, N., May 5th, 1906.

SMALL-POX IN THE "THREE TOWNS."

To the Editors of THE LANCET.

SIRS,—Those who have read the annotation in THE LANCET of May 5th concerning the outbreak of small-pox in the Three Towns (Plymouth, Stonehouse, and Devonport) are liable to entertain a misapprehension as to the total number of cases. The 214 cases mentioned have all occurred in Plymouth but there have also been 23 in Devonport and 17 in Stonehouse. Although the Three Towns are practically contiguous they are under separate municipal government. With regard to vaccination in Devonport many are quite unprotected and revaccination is very little sought after. Our first notification was received on Sept 30th, 1905, and we have had intervals as long as three and 11 weeks between the cases. I attribute the comparative immunity of Devonport to the fact that all contacts who can be prevailed upon are not only vaccinated but isolated as far as it is in our power till the incubation period is over. With four exceptions none of the cases which have occurred in Devonport have been traced to a pre-existing case, the rest having originated from contact with the disease outside the borough. So far there has not been a fatal case in Devonport although some of them have certainly been of a rather severe type.

I am, Sirs, yours faithfully,

O. HALL,
Medical Officer of Health.

Devonport, May 5th, 1906.

BLINDNESS AND THE KINEMATOGRAPH.

To the Editors of THE LANCET.

SIRS,—The transmission of light through the eye, "the window of the soul," may revolutionise the modes of producing anæsthesia, since very recently Professor Redard claims that he can produce a condition of general anæsthesia sufficiently deep for the painless performance of any operation of short duration by causing the patient to gaze fixedly on an electric light of 16 candle power inclosed in a blue glass globe, the patient's head and the lamp being covered with a blue cloth so as to exclude all natural light. He holds that each of the primary colours has a definite and characteristic effect on the higher nerve centres, red light having an exciting, yellow a depressing, and blue a calming influence. A case which recently came under my notice demonstrates the effect which an intense white light, such as is necessary for a kinematograph exhibition, may have on the sensitive retina.

A young lady, aged 21 years, consulted me with regard to what she called "a sort of blindness." The history was that up to the time she had witnessed a kinematograph display of about 15 or 20 minutes' duration she had "good vision and strong eyes," but that when leaving the hall she experienced a difficulty in seeing objects and felt as if she were entering a darkened room. This continued for two or three hours and then, as adaptation of the retina gradually took place, objects became more distinct. She had considerable headache, a sensation of dazzling, and spasmodic contraction of the eyelids. These symptoms remained for about country as well as town practitioners. The fee for the whole course of 15 lectures is £3 3*s*.

University of Durham Convocation.

On Saturday, April 28th, a convocation for the conferring of degrees was held in the great hall of the Durham University College of Medicine, Newcastle-upon-Tyne. As usual, the ancient pomp and glory of such a ceremony were kept up and the many-coloured gowns of the numerous professors and lecturers made a picturesque sight. Many guests had been invited for the occasion and the assemblage was a large one. There was a paucity of students but they did their best to cheer their comrades, though their hilarity seemed much less than in previous years. The Very Rev. Dean Kitchin, the warden of the University, presided. The degree of M.A. was conferred by vote of convocation upon Dr. James Limont, lecturer on medical jurisprudence in the Durham University College of Medicine. The degree of M.D. was conferred on six Bachelors, 19 gentlemen received the M.B. degree, and 18 the B.S., and the M.D. degree for practitioners of 15 years' standing was conferred on seven successful candidates. One gentleman received the B.Hy. and another the degree of B.Sc. The appointment of examiners in science and the confirmation of alterations in the University regulations dealing with the preliminary study for science degrees concluded the convocation. Afterwards most of those who took part in the proceedings were guests of the College of Medicine at a luncheon served in the council room.

Prevention of Consumption.

At the meeting of the county council of Northumberland on May 3rd the medical officer of health, Dr. J. W. Hembrough, made the following recommendations for reducing the amount of consumption in the county:—

1. Contributing to the funds of the sanatorium awaiting completion near Barrasford, which would enable a beginning to be made with isolation.
2. Arranging for notification (either voluntary or compulsory) of consumption.
3. Making indiscriminate expectoration a punishable offence.
4. The disinfection of rooms occupied by a consumptive patient or from which a consumptive person has been removed.
5. Facilitating the destruction of infective expectoration by providing, free of cost in necessitous cases, cheap flasks or paper handkerchiefs.
6. The appointment of lady health visitors or trained nurses who have gone through a course of instruction in hygiene.
7. Adopting and enforcing regulations under the Dairies, Cowsheds, and Milkshops Order and thus ensuring a milk-supply produced under more sanitary conditions.
8. More energetic action in the case of insanitary houses and their surroundings.

In connexion with these recommendations it is of interest to note that the Barrasford Sanatorium is rapidly approaching completion and is considered to be worthy to be classed with the best in the kingdom, but, unfortunately, it is necessary that some £5000 be forthcoming before the institution can be opened for the reception of patients. The committee, however, is making a great effort and it hopes that it may be able to receive patients this season.

Durham County Hospital: Convalescent Home.

This institution was opened at Harrogate on April 28th by the Right Hon. John Lloyd-Wharton. The home is situated in Cornwall-road, near Harlow Moor, within a few minutes' walk of the Kursal and its grounds. The building is a two-storeyed one with a basement and is constructed of Wakefield red bricks with white stone facings. Altogether there is accommodation for 22 patients, the matron, nurses, and staff. About £5500 of the required £6000 spent on the building have been subscribed, the funds having been liberally supported by the gifts of the Ecclesiastical Commissioners, Lord Durham, Mr. Lloyd-Wharton, and the colliery owners, while the miners themselves have honourably carried into effect the promise of subscriptions made some four years ago. The home is not in any way endowed and will require an income of from £600 to £700 but there should be little difficulty in raising this sum from so thickly populated a county as Durham, the mining population of which will, for the most part, reap the benefits of the home.

May 8th.

LITERARY INTELLIGENCE.—Mr. Werner Laurie will shortly publish for Dr. Ernest Walker a volume entitled "Modern Medicine for the Home."

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Pauperism and Vagrancy.

IN his opening address to the members of the Poor-law Conference which met at Malvern on May 1st, the President (Sir William Chance) drew attention to the great difference in the incidence of pauperism in the West Midland counties. In Warwickshire 19·5 per 1000 of the population were paupers, while in Herefordshire the proportion was 35·5 per 1000. Still more striking was the reference to individual unions. In the Clun union in Shropshire there were only 21·1 paupers per 1000 of the population but in the Dore union in Herefordshire there were 52·6 per 1000, although the two districts were similar in many respects. This great difference is no doubt due, as Sir William Chance stated, to laxity of administration, although some members of the Dore board of guardians have sought to justify their action by stating that the proportion of aged persons in the Dore district is higher than elsewhere. This is hardly correct, however, for at the last census there were in Dore out of every 1000 persons living at all ages 164 over 55 years of age, while in the Hereford union there were 171, in the Leominster union 175, and in the Weobley union 175 per 1000. These are all Herefordshire unions and in each the amount of pauperism is less than that which prevails in the Dore union. Sir William Chance, who was a member of the Departmental Committee on Vagrancy, said that the committee's plan of dealing with vagrants would get rid of a large number of casual wards and would bring the whole vagrant population under undivided control. The question of vagrancy had never been dealt with in a thoroughly scientific manner. The treatment of the vagrants had been left to the whims and wishes of local administrators and failure had resulted in the main from a want of uniformity. The Conference ultimately carried a motion endorsing the recommendations of the departmental committee.

The University of Wales.

A meeting was held on April 30th at the Royal College of Physicians of London to consider and to prepare the draft of a statute to establish a faculty of medicine for the University of Wales. Sir Isambard Owen (Senior Deputy Chancellor) presided and there were also present Sir Richard Douglas Powell, Dr. Donald MacAlister, Professor D. Hepburn, Professor J. B Haycraft, and Professor E. Jones.

Temperance Posters in Cardiff.

The health committee of the Cardiff corporation decided a few weeks ago to issue large placards pointing out the evil effects of drinking alcoholic liquors. When the recommendation of the committee came before the town council the town clerk, in reply to questions from some of the members, stated that there was no authority in the Public Health Acts or elsewhere for the expenditure of money for such a purpose. He was reminded that posters drawing attention to the importance of vaccination have from time to time been issued at the cost of the corporation, but he refused to be cross-examined, and in the end it was decided to take no action in the direction indicated pending the receipt of replies to communications which have been sent to some of those towns where no difficulties have been raised in connexion with the exhibition of the temperance posters.

Insanitary School Buildings.

The medical officers of health of two suburban districts in Glamorganshire refer in their annual reports to the need for improvement in the sanitary surroundings of some of the public elementary schools. Mr. T. J. Webster says that one of the "provided" schools in Vaynor and Penderyn, a district which adjoins Merthyr Tydvil, is very unsatisfactory, the walls and woodwork are dirty and badly need recolouring and painting, the lavatories are most unsuitable, and the flooring of them is in a very damp state from the overflow from the basins due to the waste-pipes being choked. In the Llandaff and Dinas Powis district which adjoins Cardiff Dr. R. Prichard describes the lighting of many of the elementary school buildings as unsatisfactory, and one school in particular he describes as being damp owing to the very easily remedied defect of dilapidated rainwater gutters. Other conditions described by Dr. Prichard are not at all creditable to the school managers.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Medical Guild.

THE Manchester Medical Guild pursues the objects for which it was founded with quiet persistence. One of these has been to watch the proceedings of those who in promoting the interests of their special philanthropic pets, the provident dispensaries, sometimes forget to do full justice to the medical profession, without the aid of which their schemes must collapse. One of these cases occurred some time ago but a satisfactory completion is only announced in the report for last year which has just been issued. A qualified medical man was charged before the General Medical Council with "accepting and continuing to hold the appointment of paid medical officer to the Rusholme and District Provident Dispensary, an association which systematically practised canvassing for the purpose of procuring patients." The General Medical Council held that the facts were proved and expressed its sense of their gravity but mercifully adjourned the consideration of the case to its next session so as to give the delinquent the opportunity of satisfying the Council as to his conduct in the interval. The matter has ended happily by the gentleman having ceased to act as medical officer to the Rusholme Dispensary. The Guild has thus been the agent of recovering to the fold one who had been tempted away and of saving him from a position that would have been unbearably invidious to any sensitive, right-minded person. One of the curious things about the promoters of these institutions is that they are honestly philanthropic in their intentions, but in their wish to help one section of the people they are careless or blind to the wrong they propose to practise on another section. This blindness is, one would suppose, not often found in minds packed full of legal subtleties, or is it, indeed, on the other hand, the result of entanglement in a mesh of fallacious sophistries? It was largely in consequence of the above case that on Dec. 1st, 1905, the General Medical Council issued a general warning against advertising or the employment of agents or canvassers to obtain patients. The working of the Midwives Act has received much attention by the council of the Guild and an important letter was elicited from the Local Government Board stating that under the Public Health Act of 1875 and the Poor-law Amendment Act of 1848 local authorities could, with the consent of the Board, pay fees to medical men in such cases. Acting on this letter the corporation of Manchester obtained permission from the Local Government Board, and for this purpose allowed in the city estimates for the year a sum of £500. The suggestions of the Guild council have been adopted almost in their entirety by the British Medical Association, especially upholding the principle that "attendance on midwives' cases should be open to every member of the profession." The city council decided on a maximum fee of 21*s*. Attention has also been directed to other matters interesting to the profession—e.g., the relations of general practitioners to operating surgeons, testimonials from medical men in favour of proprietary medicines, the proposals of the British Medical Association as to a public medical service, vaccination law amendment, &c. Nowadays every cause has its organ in the press and the *Guild Quarterly* sustains its part with an energy and talent not always found in more pretentious literary ventures.

Adulteration of Food.

Judging from the Lancashire county analyst's report for the quarter ending March 31st last, the chief victims of adulteration are children, as the principal consumers of milk, and those adults who indulge more or less in alcohol. It appears that 795 samples were analysed under the Sale of Food and Drugs Acts, 43 of which offended against the law. Of milk 235 samples were examined, 21 of which were below the required standard. 144 samples of spirits for consumption were analysed and came out better than the milk, only seven of them being faulty. In addition to these 40 samples of whisky were examined, and found to consist mainly or entirely of patent-still spirit. Milk, which is so rapidly perishable and so easily contaminated, offers special temptation to the fraudulent, either by dilution or the addition of preservatives. Æsthetically the most revolting contamination is from the too often filthy hands of the milker, for it is a far cry to Izaak Walton's idyllic milkmaid from the unwashed udder and the occasional splash into the can of the ordure-laden tail. It is strange that while so much attention is being paid to these matters too many of the farmers have scarcely the most primitive instincts of cleanliness. Of course, there are exceptions and the sooner they become the rule the better. Then in most farms little heed is paid to protecting the milk from microbe-laden dust on its way from the cow to the consumer. Altogether, we are in a very backward condition as to the management of our milk-supply, and it is not to our credit. The wonder is not that disease is conveyed by milk but that so little harm, on the whole, is done. The last does not seem to be heard of the rival pot-still and the patent still.

Dainty Food!

We now and then get infamous foodstuff sent to Manchester but a good deal of it is intercepted before further mischief is done. At Macclesfield the other day the magistrates were told of the following suggestive case. A dealer bought a cow for 10*s*. 6*d*. and sold it at a handsome profit for 30*s*, when it was killed and no doubt skilfully dressed by the slink-butchers and the meat sent to Manchester as food for the people.

The Care of the Blind.

On Saturday last a conference was held in Manchester under the auspices of the Manchester and Salford Blind Aid Society, at the St. John-street branch of the Royal Eye Hospital, on matters relating to those blind persons who live outside institutions. When we think of the few blind people met with as we go through the streets it comes as a surprise that in 1901 the returns showed that there were 25,317 in England and Wales. Of these 5676 were employed in some profession or business, while 2560 were provided for industrially in workshops and institutions. Representatives from various societies and institutions throughout the country were present and it is encouraging to know that these unfortunate and often necessitous persons are not forgotten. The holding of local conferences from time to time was advocated not only as conducing to coöperation and so preventive of overlapping but as attracting the attention of the public to the work and its needs. The claims of workshop employment for the blind was strongly advocated for those who had completed their training and were qualified to do some kind of work. It secured constant work, a living wage, and proper oversight and care.

Manchester Jewish Hospital.

An appeal for help for the Manchester Jewish Hospital has been issued, the response to which ought not to be limited to one section of the community. Though, of course, there is much wealth among the Jews, it is accompanied in Manchester by much poverty. The benefits of the institution are open to all deserving applicants without distinction of creed and are fully appreciated by non-Jews. But there is a debt on buildings and equipments of £3500 to be cleared off and an annual deficit of about £550. This is a fair sample of such appeals. The institution is deserving and well managed, but each repetition of the well-known story marks the urgency of the question, What is to be the future of our hospitals?

Bequests.

Mr. Horatio Bright of Lydgate Hall, Sheffield, left large bequests to medical charities, £50,000 to the Buxton Bath Hospital, £10,000 to the Manchester Infirmary, £10,000 to the Leeds Infirmary, and £10,000 to Guy's Hospital. He left also £20,000 to the National Lifeboat Institution. "He directed his body to be taken to his mausoleum at Moscar Rest on a dray and there laid without any religious or other service."

May 8th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Post-Graduate Instruction.

A COURSE of lectures and demonstrations has been arranged in connexion with the Royal Infirmary, Newcastle-upon-Tyne, and will be carried out during the months of May, June, July, and September. The lectures will be delivered by the honorary staff of the Royal Infirmary on Wednesdays at 4 P.M. and 8 P.M. alternately to suit the convenience of

Senate on May 4th when the following motion was adopted unanimously:—

> That, having regard to the official pronouncement made in the House of Commons on March 15th by the Chief Secretary that His Majesty's Government had been advised "that the Senate of the Royal University of Ireland had the power to maintain order, and to take all steps necessary to that end," the Senate hereby direct the standing committee to prepare a draft of such statutes and regulations as shall provide the necessary means to enforce academic discipline and to punish academic misconduct.

In reference to the disorder last October it was directed that the minutes of the Senate meetings, &c., relating thereto should be supplied to the Government.

The Health of Belfast.

The public press in Belfast is at present full of communications dealing specially with the problem of consumption in Belfast. It would appear that for 12 years past the average annual death-rate from pulmonary tuberculosis has been 3·3; in 1894 it was 3·8, and in 1895 it was 3·1, a death-rate almost twice as high as any corresponding city in England or Scotland. Further, from pulmonary tuberculosis alone over 1000 people die every year in Belfast, and if the other types of tuberculosis be included it is calculated that 1500 of the Belfast citizens die annually. On May 4th the announcement was made that the medical officer of health had resigned and on May 8th there was a great meeting of the citizens under the auspices of the Citizens' Association to consider the deplorable state of the public health in Belfast. Not for years has so much public opinion been aroused on any question in Belfast as there is at present as to the public health, and it is hoped that some good will accrue and that really practical measures will be adopted.

Insanity in Ireland.

The Royal Commission on the Care and Control of the Feeble-minded heard evidence in Dublin on May 5th, when the Irish Registrar-General, Mr. R. E. Matheson, LL.D., stated that in 1861 the proportion of lunatics and idiots to the population in Ireland was 1 in 411; 25 years later it was 1 in 281; and in another 20 years, in 1901, it was 1 in 178. There have been increases of insanity in England and Scotland but not to the same extent. In England and Wales the proportion of insane per 10,000 of population increased between 1871 and 1901 from 30·39 to 40·79; in Scotland the increase was from 33·97 to 45·37; while in Ireland the increase was from 30·49 to 56·18. Of the causes for this terrible state of affairs in Ireland Mr. Matheson mentioned three: First, the return from the United States of Irish men and women who have lost their health and reason while working there. In Ireland they were supporting not only their own lunatics but a considerable number drawn from the Irish population of America. He advises that severe penalties should be imposed on shipping companies who attempted to land persons of unsound mind without the Lord Lieutenant's licence. Secondly, heredity. No person who has been detained as a lunatic or an idiot should be allowed to marry without the special permission of the Lord Chancellor, obtainable only after a full consideration of the circumstances. Thirdly, drink. No doubt the emigration from the country of a large proportion of the young and healthy and a return to it of those whose reason has been affected while in America have a good deal to do with the increase of insanity in Ireland.

May 8th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Operative Decortication of the Lung.

AT a meeting of the Academy of Medicine held on April 10th M. Picqué gave details of the case of a man, 21 years of age, who in July, 1905, was stabbed with a knife in the right interscapular region on a level with the fourth intercostal space. When taken to a hospital the patient presented all the signs of extensive hæmothorax, accompanied by severe dyspnœa, pyrexia, &c. Thoracotomy was immediately performed and resulted in the escape of a litre of blood mixed with clots. As the patient's condition did not improve partial resections of ribs were performed several times in the course of the ensuing months but without benefit, until a final resection, more extensive than the others, showed that the right lung was completely immobilised by the visceral pleura which was considerably thickened. The greater portion of this pleura was then resected according to the method of Delorme, after which the lung immediately became released and formed a hernial protrusion between the edges of the pleural incision. From this date the patient rapidly improved and he may now be considered as quite recovered.

Medical Excursions.

The eighth medical excursion will take place from Sept. 1st to 12th and will be under the general direction of Professor Landouzy. The places to be visited are health resorts in Savoy and Dauphiné; they will include Hauteville (where there is a sanatorium), Évian, Thonon, Saint-Gervais, Chamonix, Annecy, Aix, Marlioz, Le Revard, Challes, Salins-Moutiers, Brides, Pralognan, Allevard, Bonquéron, La Motte, and Uriage. 12 grants in aid of the expenses (*douze bourses de voyage*) will be made on the occasion of the excursion in 1906. These grants are directed by their founders to be awarded as follows: (1) to an English, a Belgian, a Danish, and an Italian medical man; (2) to two medical members of the Concours Médical and of the General Association of French Medical Men; (3) to two resident medical officers (*internes*) of Paris hospitals; and (4) to a student of each of the medical faculties of Bordeaux, Lyons, Paris, and Reims. For further information application should be made to Dr. Carron de la Carrière, 2, Rue Lincoln, Paris, or to Dr. Jouaust, 19, Rue du Colisée, Paris.

A New Thermo-cautery.

At a meeting of the Surgical Society held on April 11th M. Routier showed for M. Granel a new thermo-cautery in which light mineral oil is burned. Its special feature is that the reservoir for the oil is very small, has inside it a sponge soaked with the oil, and is entirely contained within the handle of the cautery, an arrangement which is a great convenience in using the instrument. The reservoir cannot explode and holds sufficient oil for four hours' work. There is a special device for regulating the temperature of the cutting edge and the cautery will act even when introduced into cavities containing much fluid.

The Medical Service of the Navy.

A regulation has been recently made, according to which young men admitted either to the chief naval medical school or to the naval training school (*école d'administration de la marine*) or to administrative duties in connexion with the naval reserve (*inscription maritime*) shall, on entering the school or on being nominated to an appointment, bind themselves to remain on active service for at least six years from the date of receiving the rank either of medical officer or dispenser of the third class, or of assistant medical officer or assistant dispenser of the second class, or of clerk of the third class.

The Family of the late Professor Curie.

The Council of Ministers has decided that on the reopening of Parliament the Minister of Public Instruction and Fine Arts shall submit to the Chamber of Deputies a Bill to provide a pension (*pension nationale*) for Madame Curie and her children.

The Strike of Printers.

In consequence of the printers being on strike several important medical journals have been unable to appear at all during the last two weeks and others have been considerably delayed. It is to be hoped that this unfortunate state of affairs will not continue much longer.

Pulmonary Gangrene after Attempted Suicide by Drowning.

At a meeting of the Société des Hôpitaux M. Bergé read a paper on the case of an insane woman, 31 years of age, who threw herself into the Seine at Paris last winter. Rescued in an unconscious state and removed to a hospital she suffered from two successive varieties of pulmonary lesion at several days' interval. At first there was at the base of the right lung an area of broncho-pneumonia and then at the base of the left lung there was an area of pulmonary gangrene with fœtor of the breath and of the expectoration. These two conditions, both of which terminated in recovery, were evidently caused by the bacteria of sepsis and of putrefaction contained in the Seine water which had made its way into the air passages. The coldness of the water and the mental depression which instigated the suicidal attempt would probably assist in the development of the pathological processes.

May 7th.

Appointment of a Medical Officer of Health at Chipping Sodbury.

At a meeting of the Chipping Sodbury rural district council held on May 3rd a letter was read from the Local Government Board inclosing draft copy of a provisional order for union of districts under Section 286 of the Public Health Act, 1875, for the appointment of a medical officer of health and requesting any remarks from the council upon the subject. The order is to unite the following district councils by appointing a joint committee of 18 from them—namely, Awre, Cirencester, Newnham, Tetbury, and Westbury-on-Severn urban districts, and Chipping Sodbury, Cirencester, East Dean, Gloucester, Lydney, and Tetbury rural districts. The letter added that Chipping Sodbury having given notice of objection this procedure was necessary, and the Local Government Board further stated that the officer appointed must submit to the joint committee copies of every report which he makes in regard to any part of the district and any difficulties arising will be finally decided by the Board. After a long discussion, during which a motion was proposed "That the council offer no opposition to the provisional order" and was defeated, an amendment was carried by 11 votes to 4 that the "council protests against the action taken by the Local Government Board."

Aberystwyth Board of Guardians and its Medical Officer.

At a meeting of the Aberystwyth board of guardians held on April 30th it was decided to reappoint Mr. G. R. E. Bonsall as medical officer to the workhouse, provided that he agreed to the appointments held by him under the guardians being included in one appointment, and to increase his salary by £15 per annum.

May 8th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh: Meeting of the General Council.

IN THE LANCET of May 5th, p. 1266, there was published an abstract of the business to be brought before the meeting of the council held on May 2nd, in so far as it dealt with matters of medical interest. It may be recalled that a new draft ordinance was submitted to the council proposing important changes in the medical curriculum. The draft ordinance had been in the hands of the very capable business committee of the council for some time, with the result that not only the draft ordinance but the amendments and additions proposed by this committee to be made to it were in the hands of the members of the council before the meeting. The report of the business committee was submitted by its convener Mr. Buchan and seconded by Sir James Russell. Professor D. J. Cunningham, Dean of the Faculty of Medicine, while supporting the report, took some exception to the clause providing that students might be prevented attending more advanced classes when they had not passed the earlier examinations; he did not, however, press this point, with the result that the report was unanimously adopted. When Mr. Buchan submitted the report he read a letter from Principal Sir William Turner in which he said: "The report of the business committee has been sent me and I have read it with much interest. Many important questions have been under consideration and I have been specially interested in the part referring to the medical ordinances. The import of the proposed changes has been stated with lucidity and I hope that the committee's recommendations will be adopted." After the part of the report dealing with the proposed changes in the medical curriculum had been thus unanimously passed, the portion which dealt with the method of legislation by ordinance was submitted by Mr. Buchan and seconded by Sir Andrew Mure, who dwelt upon the extraordinary fact that the universities of Scotland were tied hand-and-foot in the matter of legislation. This was also unanimously approved, the council deciding that it should be represented to the University Court that (*a*) the time has now come when the Government and Parliament should be asked to confer upon the Scottish Universities severally a large measure of autonomy; and (*b*) the business committee should take steps, either in conjunction with other academic bodies or otherwise, to forward the matter. Two other minor proposals were approved by the council: (1) That the hour of meeting for the future should be half-past three; and (2) that the notices of meetings and reports should be posted to members of the council in England, these hitherto being only sent to members resident in Scotland.

Small-pox in Glasgow.

In THE LANCET of April 28th, p. 1212, reference was made to a case of small-pox occurring in an alien emigrant while passing through Glasgow *en route* for America. Dr. A. K. Chalmers, medical officer of health of Glasgow, pointed out at that time the risk arising from the present method of housing alien emigrants and the force of this criticism has had an unfortunate illustration during the past fortnight. Since the removal of the first patient to Belvidere a frequenter of the hotel in which he was lodged has developed the disease and it is worthy of note that this patient's room was on the same floor as that occupied by the emigrant who first developed small-pox. As several inmates of the hotel had visited this second patient in his room before the symptoms had fully developed it was found necessary to isolate them, and on account of difficulty experienced in inducing them to comply with the suggestions made a warrant under the Public Health Act had to be obtained for the purpose. If there is any risk of small-pox being introduced and spread in this way by alien emigrants it is far from reassuring to note that of the 311 foreign emigrants housed in one week last month by the shipping companies prior to the departure of their vessels 63 were lodged in eight lodging-houses and one hotel in which non-emigrants also were accommodated.

May 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Rotunda Hospital, Dublin.

A "CHARTER" meeting of the board of guardians of the Rotunda Hospital was held on May 4th, Mr. O'Brien Furlong, C.B., presiding. Dr. R. D. Purefoy and Dr. James Little gave notice that at the next "charter" meeting of the hospital they would move:—

> That Mr. F. T. Heuston, the consulting surgeon to the hospital, be elected to the vacancy on the board caused by the death of the late Sir William Findlater.

Notice was given by Dr. Purefoy and the Master that at the next meeting of the board they would move and second:—

> That a consulting oculist to the hospital be appointed.

Surgeon-General C. Sibthorpe, I.M.S., C.B., F.R.C.P. Irel., L.R.C.S. Irel.

I regret to announce the death of Surgeon-General Sibthorpe which took place on May 4th at his residence, 38, Upper Leeson-street, Dublin. He served in the Burmese campaign of 1885-86 and received honourable mention with the medal and clasp. He also served as deputy surgeon-general in the Afghan war, for which he was mentioned in despatches and received the medal. The late surgeon-general was the author of an important work on "Indian Clinical Research" and of various essays and treatises on medical subjects. He was born in 1847 and was therefore in his fifty-ninth year.

Royal University of Ireland.

At the recent M.B. examination of the Royal University of Ireland a first-class exhibition (£40) was awarded Mr. Robert Jamison of Queen's College, Belfast, and a second-class exhibition of £25 to Mr. W. J. Leighton of Queen's College, Belfast, while another candidate, Mr. W. A. McKee, obtained first-class honours in medicine and second-class in surgery. All the honour distinctions of the M.B. went to students of Queen's College, Belfast. At the second examination in medicine Mr. James M. O'Connor, from the Catholic University School of Medicine, obtained first-class honours and a first-class exhibition of £25, while at the third examination in medicine Mr. W. D. O'Kelly, Catholic University School of Medicine, obtained a first-class exhibition of £30, and Mr. Marshall F. Huston of Queen's College, Belfast, was awarded a second-class exhibition of £20.—Some little excitement was caused among the rowdy section of the undergraduates of the Royal University by a recent article in the *Times* advocating their being punished and by Mr. Bryce's statement in the House of Commons on May 3rd that the Senate had the matter under consideration. There was a full meeting of the members of the low sick-rate and shows an excellent state of health of the labourers.

Yellow Fever Inspection and Publicity

The city of New Orleans suffered so severely from yellow fever last year from the inefficiency of health authorities that the citizens are taking early precautionary measures against the mistakes then apparent. At a large and representative gathering of citizens recently it was determined to render the city immune against this pestilence, a condition which they believed entirely possible by the strict enforcement of the anti-mosquito ordinance and such other sanitary measures as can be readily undertaken. The meeting earnestly urged each of the ward organisations to perfect its inspection service and pledged the funds necessary to carry on the work. This determined action of the citizens to take all needful precautionary measure against a repetition of last year's experience is extremely encouraging. The Parish Medical Society met soon after and resolved to enforce immediate reporting of every case by physicians, declaring "That any member of this society failing to make such a report will be deemed guilty of unprofessional conduct and be tried for such."

The Standard of Immigrants Raised.

The new immigration Bill before Congress fixes a higher standard for immigrants than has ever prevailed. The head tax is raised from $2 to $5; the educational test requires that every person above the age of 16 years admitted to the United States shall be able to read some language, every adult male immigrant must have at least $25 at the time of landing and every adult female immigrant at least $15, but heads of families may be admitted with their entire families provided they have $50. It places in the excluded class imbeciles, the weak-minded, and manual labourers of poor physique and gives the Department of Commerce and Labour discretion to admit or exclude immigrants under 16 years of age coming to this country alone.

The Philippine Medical Association.

The report of the annual meeting of this association is full of interest, as its proceedings illustrate the progress of medicine in the islands. The meeting was held on Feb. 28th, under the presidency of Dr. Victor G. Heiser. The association was addressed at its opening by the Secretary of the Interior, the Hon. Dean C. Worcester, formerly of Ann Arbor University, Michigan, who stated that the number of medical practitioners, good, bad, and indifferent, was absurdly small; there was one physician to every 18,399 inhabitants, and, outside of Manila, there was only one to each 50,455 inhabitants; and in a number of provinces there was no medical man of any description. He stated that the Japanese had conferred incalculable benefit upon medical science by their recent demonstration of what could be done to combat epidemics and to protect soldiers and sailors in war. The relations between the medical officers of this Government and those of the Japanese Government had been of the friendliest and most helpful character. In the early days serums and prophylactics were furnished by the Japanese. The control of the cholera epidemic by modern methods had been an impressive lesson to the people of the islands and especially important had been the preparation of cholera vaccine by the director of the Biological Laboratory, which had been proved to produce an extraordinarily high blood immunity against that disease. The Secretary spoke of the necessity of improving the hospitals and concluded by highly complimenting the work of the medical profession. The President, Dr. Heiser, reviewed the progress of medicine in the islands and stated that medical science held the key to the prosperity of the people; the last year had been of great importance in regard to medical progress by the passage of the Act establishing a medical school. The Philippines with an educated native medical man for every 1000 inhabitants would be a very different country with a different history; educated Filipino sanitarians were needed. Since the last meeting St. Paul's Hospital had been established in Manila; the Episcopal Church had completed the necessary arrangements for establishing a general hospital; the Methodists had opened a dispensary and were soon to have a maternity hospital in operation; the navy had completed a hospital at Canacao in Cavité; the army had completed another at Fort William McKinley; the Government had established a sanatorium in the mountains of Benguet; dispensaries were now operated by church organisations or by the Board of Health at many places throughout the provinces, while the indigent poor had been supplied with large amounts of medicine in remote districts. Many interesting papers were read during the sessions of the association and the spirit manifested was of the most inspiring character.

April 20th.

Obituary.

MATTHEW BAINES, M.D. LOND., M.R.C.S. ENG.

THE death occurred on Saturday last, May 5th, of Dr. Matthew Baines, of Cranley-place, South Kensington, one of the best-known and most highly respected general practitioners of the neighbourhood. Dr. Baines was educated at King's College, London, and entered the medical school of King's College Hospital more than 60 years ago, when George Budd and R. B. Todd were the physicians on the staff and William Fergusson and Richard Partridge the surgeons. He was therefore a contemporary at the school with Dr. Lionel Beale whose death we chronicled a few weeks ago. In 1845 Dr. Baines obtained the diploma of M.R.C.S., becoming also a Licentiate of the Society of Apothecaries of London; a little later he graduated in the University of London as M.B., obtaining the University medical scholarship and the gold medal for medicine. He was therefore marked out from the first as one who was going to succeed in his profession. After a course of study in Paris, at that time a usual proceeding with the more ambitious among English students, and after filling various minor appointments he proceeded to the M.D. degree and settled down in general practice. For very many years he practised in South Kensington where he was regarded as the *doyen* of the profession and where his wide scientific and general knowledge, his unfailing courtesy, his frankness, his charity, and his strict respect for professional methods gained him the esteem not only of a large number of patients but of all his medical brethren. "Dr. Baines was especially anxious to support all movements that might bring the medical man into closer touch with the public," writes an old friend, "and his interest in the Volunteer movement and in ambulance work *shows this.*" He was a Surgeon Lieutenant Colonel in the 1st Middlesex Volunteers and possessed the Volunteer Decoration and was also a Knight of Grace of the Order of St. John of Jerusalem. He was also on the council of, and local secretary for, Epsom College. Until quite lately Dr. Baines had borne his years well but recent family bereavements had tried him sorely. He practically died in harness, a veteran universally respected.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Vincent Paulet, formerly professor of anatomy in the University of Montpellier.—Dr. Karl Fürstner, professor of mental diseases in the University of Strasburg.—Dr. Max von Braun, formerly body physician to the King of Bavaria. He was the son of Professor Jacob Braun.—Dr. R. Thomé, *privat docent* of anatomy in the University of Strasburg.—Dr. Ludwig Kleinwaechter, formerly professor of midwifery in the University of Innsbruck. He contributed a number of articles to Eulenberg's Real Encyclopädie and to Hirsch and Gurlt's Biographical Dictionary of Medical Men.—Dr. Benjamin S. Roseberry, formerly professor of materia medica in the Baltimore University.—Dr. John B. MacCallum, assistant professor of physiology in the University of California, San Francisco.

PRESENTATIONS TO MEDICAL PRACTITIONERS.—Mr. Octavius Edward Bulwer Marsh, M.R.C.S. Eng., L.R.C.P. Edin., J.P., of Newport, Monmouthshire, was, at the Newport Constitutional Club on April 28th, presented with a silver tray and a pair of silver jardinières as a mark of respect and esteem on the occasion of his "silver wedding."—On May 1st Mr. G. L. Kerr Pringle, M.D. Edin., of Whitley Bay, Northumberland, was made the recipient of a Jacobean tea service, together with a sum of money, as a mark of esteem and respect on his leaving the district. Dr. Pringle has only resided in Whitley for a few years but the popularity which he has gained in that time was shown by the way in which the testimonial was supported and by the enthusiasm displayed by his friends at the presentation.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Sixth International Congress of Criminal Anthropology.

ONE fact which emerged from the discussions at this last and, on the whole, most successful of the International Congresses of Criminal Anthropology would suffice of itself as a *raison d'être* of the series—namely, the increase of juvenile crime and the progressively younger age of the criminal. Professor van Hamel of Amsterdam, M. Louis Albanet, juge d'instruction in the High Court of Justice in Paris; M. Paul Kahn of the Parisian bar, and the Signorina Ida Faggiani of the "Istituto dei Frenastenici" in Turin, all of whom read papers on the subject of juvenile crime, were at one on this gravely significant fact. Professor van Hamel led off with a luminous survey of the whole field of "young delinquency" and proceeded to suggest some drastic reforms in the traditional modes of dealing with it. The practice of segregating juvenile criminals *en masse* he would replace by the process of "selection" after a methodical and practical examination of each individual case. Treatment of the penal kind, whether in prison or penitentiary, ought, he urged, to partake more and more of the educative character, approaching as nearly as circumstances admit, to the family ideal. So conceived, the "punitive" discipline should be graduated in the order: (1) of admonition; (2) of amendment; (3) of brief sojourn in a house of correction; (4) of conditional condemnation to such a house; (5) of systematic and specialised education up to adult years in a Government institution; and (6) of emigration. All cases which after the adult age continued to show themselves incorrigible and dangerous would have to be subjected to surveillance, vigilant and systematic, in houses organised *ad hoc* (*maisons de santé*, houses of labour, and such like). Bold and comprehensive as are Professor van Hamel's proposals, he contends that they are quite practicable and have indeed been carried out with gratifying results in the United States of America. Expensive they would undoubtedly be to put in working but in the long run they would be a source of economy to the body politic. Italy in particular, where crime attains such formidable proportions, would find it cheaper to make a trial of Professor van Hamel's proposals than to continue in the vicious evils in which she has long been gyrating—adding yearly to her prison accommodation and prison staff only to send out the criminals (often prematurely) more than ever prone to crime and proficient in its ways. Not a few of the Dutch professor's auditors who took part in the discussion were even prepared to institute the "juvenile courts of justice" so successful in some of the States of the American Union—courts specially fitted to deal with young offenders, to take note of their individual characters, moral and physical, and to put them under influences conducive to their rehabilitation. Following on Professor van Hamel's lines, M. Louis Albanet reported very favourably on the "Patronage Familiale" as carried out in Paris—a medico-pedagogic clinique—the working of which was still further illustrated by M. Paul Kahn in a paper which sent something like a thrill through the audience in its accounts of the increasingly early age at which the young delinquent is taken up. Some cases, indeed, are nearer the infantile than the boy aged Monday's sitting (April 30th) was chiefly interesting for a brilliant paper by Signor Enrico Ferri who sits in the Italian Parliament for the constituency of Gonzaga. His theme was

The Prophylaxis and Therapeutics of Crime.

Assuming the position that the criminal ought, so far as possible, to be regarded as a "patient under treatment," he pleaded for a more elastic scale of punishment than that traditionally enforced in the law courts. The prison penalty determined to expire at a stated time is, he urged, quite ineffective. Either it constitutes a useless constraint in the case of individuals who have "amended themselves" before the expiry of their term, or it is without good results for those who, having served their time, are as bad as, if not worse than, before. In Italy, he said, society takes back to its bosom delinquents more formidable, more dangerous to it than ever, while it keeps in prison those whose moral rehabilitation is such as to make them useful citizens. Arguing from these premisses Signor Ferri would recommend a periodical revision of condemnations to prison, so as to admit of the restoration to liberty of those who are really reformed, while, on the other hand, prolonging the sentence of those whose criminality is undiminished, if not intensified. These bold suggestions found more encouragement from the Italian than from the other auditors, Italy feeling year by year the increasing burden of her congested prisons. The discussion with Signor Ferri's reply on the whole issue was one of the most fascinating on the agenda paper and will be found of special interest in the official report shortly to be issued. Signor Garofalo, the Venetian Procurator General, contributed a well reasoned paper in which, following on Signor Ferri's lines, he urged the necessity of instituting establishments for the detention, *in perpetuo*, of criminals declared irresponsible owing to mental incompetence. The last paper of supreme interest was that of Professor Sommer of Giessen on Recent Methods of Criminal Psychology, illustrated with graphic delineations. These latter and the reproduced "projections" which accompanied the reading of other contributions will be found an equally attractive and instructive feature in the "Atti" of the congress soon to be made *publici juris*.

May 5th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

A National Quarantine.

THE Bill creating a national quarantine in the United States has passed Congress and with the approval of the President, which is assured, will become law. The enactment of this measure marks the breaking down of the old "State Rights" prejudices which have been a bar to progress in public health legislation on the part of the General Government ever since its first organisation. This measure is, however, but a step in the right direction, for it is limited to certain ports especially liable to the introduction of yellow fever. The law is well drawn, for it gives the Secretary of the Treasury, and through him the surgeon-general of the Public Health and Marine Hospital Service, the control of all quarantine stations, grounds, and anchorages, and directs that he shall select suitable places for them and establish the same at such points on or near the sea coast of the United States, and on the Mexican border, in order to prevent the introduction of yellow fever into this country. The Bill also provides for the establishment of a quarantine station at the Dry Tortugas Islands and at such other points at or near the sea coast—not to exceed four in the aggregate—as may be deemed necessary. This legislation is the outcome of the failure of local health authorities to protect New Orleans last year from an epidemic of yellow fever.

The Abatement of the Smoke Nuisance.

Smoke has become an intolerable nuisance in many cities and large towns where there is any manufacturing industry. The abatement of this nuisance has been prevented by the absence of adequate laws in many instances and the failure of health authorities to enforce laws and ordinances in others. To meet these conditions a "Smoke Abatement League" has been organised in Hamilton County, Ohio, the purpose of which will be to secure the passage of laws, State and municipal, which will protect communities from the damage and discomfort of smoke. The league will take all necessary measures to abate the nuisance and, when compelled to resort to the courts, will undertake the prosecution of offenders. The organisation also proposes to make scientific investigations into the effects of smoke upon the public health.

Department of Health of the Isthmian Canal Commission.

Chief Sanitary Officer Gorgas states in his monthly report for February that no case of yellow fever has occurred for three months. The city of Panama has been free from yellow fever since Nov. 11th. The Canal zone is free from other quarantinable diseases, though yellow fever, plague, and small-pox are prevalent in the South American Pacific ports. Yellow fever is prevalent in the ports of the Caribbean coast, both north and south, but such is the vigilance of the Commission's health department that the pestilence can get no foothold in the communities over which it exercises jurisdiction. Of over 23,000 canal employees there is an average of 472 patients daily in hospital which gives a constant sick-rate of 20 per 1000. This is a surprisingly the character of the colour contrasts and the astigmatic conditions of the observer was so constantly obtained that the following broad generalisations were rendered permissible. 1. Coetaneous contrast colour complements are more certain, more pronounced, and more complex in positive relation with the kind, the degree, and the meridionality of the existent astigmia. 2. Coetaneous complementary colour contrasts in their primary and least complex types appear as faint red-green bands which begin as a series of marginal stripes along the watery borders, the red being the first evolutionised tint; these being the most prominent colour factors in the simpler and the more regular forms of astigmia. 3. Coetaneous colour contrast complements in their more complicated varieties superadd determinate degrees of simultaneous blue-yellow complements to the red-green series, these associated subjectivisms being fixed in form and positive in position in direct relationship with the grossness of the amount of the resident astigmia and its departure from prevalent angle. 4. Complementary colour contrasts of coetaneous types in their most exaggerated forms are always found in strict association with the highest degrees and the most bizarre types of regular and irregular astigmia.

Trachoma.

Dr. MELLO BARRETO (São Paulo) read a paper founded upon his experience in dealing with this condition, which is propagated very commonly in his neighbourhood among Italian colonists. Brazilian farm hands, he said, even in contact with the Italian colonists, rarely contracted the disease. Chibret's law, which establishes that at altitudes greater than 200 metres trachoma does not obtain, is not verified in the State of São Paulo, Brazil, where the coffee zone is always above 500 metres, so that the Italians' predisposition for the disease must lie in their race. The treatment of trachoma, he suggested, was mainly prophylactic, all close relations with sufferers are risky, and the patient should take great care not to spread the disorder by the objects of his personal use—for instance, towels and handkerchiefs. The curative treatment of trachoma among the Brazilian practitioners, he said, consisted of submucous injections under the eyelids of a 1 per cent. solution of pyoktanin. Ten drops of the pyoktanin are injected in the submucous tissue of the eyelids, with the result that at the end of an hour a great venous hyperæmia supervenes. The injection promotes a flooding of the trachomatous tissue and so an œdema is produced which smoothes off the rugous and irregular surface of the tissue. The submucous injections of the eyelid with an aqueous solution of 1 per cent. of pyoktanin should be repeated as often as the œdema produced by the treatment disappears, leaving still granulations behind. Dr. Barreto warned his audience against more drastic measures, pointing out that the scars resulting from canteries or from the crushing of the granulations are more dangerous than the granulations themselves to the ocular globe.

OBSTETRICS AND GYNÆCOLOGY.

Professor KARL HENNIG (Leipsic) discussed

The Nomenclature of Obstetrics.

He pointed out the necessity of a terminology which could be universally understood by obstetricians in all countries. Latin was employed in botany and zoology and a similar simplification of the scientific terms employed in obstetrics was called for. He presented a very exhaustive table of obstetrical terms, giving the equivalent expressions in six languages—viz., Latin, Greek, French, German, English, and Italian.

Professor CANDIDO DE PINHO (Oporto) read a paper on

The Auto-intoxications of Pregnancy.

No one disputed the saying that "every pregnant woman is in a condition of auto-intoxication." Certain of the toxic agencies had been long recognised. For example, it had long been known that the total excretion of urea and nitrogen in pregnancy was below the normal, and further, of two pregnant women, one of whom felt well and the other ill, the latter had the smaller nitrogenous excretion. Formerly many theories regarding the cause of this phenomenon had been advanced, all starting, however, with the hypothesis of renal inadequacy. Later, experimental physiology had proved the profound action of the liver on the blood and on endogenous and exogenous toxins, and this study had originated theories of hepatic insufficiency. As facts accumulated an extensive knowledge was obtained of internal secretory glands, the defences of the organism, the metabolism of nutrition, the properties of the fluids, and the action of the various cells and tissues, and at the present time the auto-intoxication of the pregnant state was interpreted as being the result of an *antitoxic insufficiency.* The toxins in the body of the pregnant woman were endogenous and exogenous, corresponding to maternal and fœtal toxins. 1. The *maternal* poisons originated from (*a*) delayed assimilation, and (*b*) the digestive tract. With regard to the first factor, the total nitrogenous excretion was diminished by 16·9 per cent. and the urea by 18 per cent.—figures pointing to mal-assimilation of albuminoid material. Those organs which influenced cellular metabolism (e.g., liver, thyroid, and ovary) were affected, and led to alterations in the pigments, the chemical reactions of the fluids, the leucocytes of the blood, and the nervous system, in a manner not yet fully determined by experimental pathology. Some women felt unusually well during pregnancy; such cases were explicable by the fact that a small quantity of toxin had a stimulating effect. With regard to the second factor, the researches of Professor Charrin had proved the importance of the intestinal toxins in pregnancy. Many vascular and hæmic changes formerly supposed to be due to cardiac and cardio-vascular disease were now recognised consequences of toxæmia of intestinal origin. These changes were briefly described and the history of several cases was narrated. 2. Toxins also originated from the *fœtus* and the *placenta.* Bordet and Metchnikoff in France, and Ehrlich and Morgenroth in Germany, had opened up an unexpectedly large field in cytology and since 1898 there had been a flood of literature on cytotoxins. A brief summary was then given of the action and nature of cytotoxins and anticytotoxins. He (the speaker) was of opinion that in the physiology of the placenta would be found the explanation of much of the problem and quoted in support of this view the biological researches of Letulle, Veit, and Schölten. The theory was well summarised by Bandler:[1] The placenta gave off into the maternal circulation elements derived from its ectoblast, trophoblast, and syncytial cells; the placenta acted upon the maternal blood and was in turn influenced. The maternal blood contained some element the function of which was to resist, modify, or counteract the placental secretion. The ovary furnished this element. Eclampsia was best explained by a mal-secretion of the placental gland or preferably a relative mal-secretion due to insufficient or abnormal modification of the placental secretion by the elements furnished by the ovaries. The auto-intoxication of pregnancy, therefore, was due to (1) increased toxins and (2) decline of the defensive power of the body, either from overwork or congenital weakness; in other words, the patient had an *antitoxic insufficiency.*

M. GUSTAVE RICHELOT (Paris) read a paper on

The Treatment of Uterine Retro-displacements.

He started by stating that, for his purpose, no distinction need be drawn between retroversion and flexion. Retro-displacements were either (1) symptomatic or (2) primary. In (1) the uterus was bound down by adhesions and parametritis might be present. Obviously the retroversion was, then, due to inflammation of the peritoneum or uterine appendages dragging the womb out of position. In such cases one of two methods of treatment might be adopted: (*a*) total extirpation of the uterus or (*b*) a conservative operation might be performed, the uterus being left while its appendages were removed. The cause of the pain and other symptoms having been removed it did not then matter whether the uterus remained in position or not. (2) The term primary retroversion did not necessarily imply the absence of any cause whatever but it did imply that the uterus was mobile, that no adhesions were present, and that the tubes and ligaments were healthy. It was found in young girls, in nulliparæ, and also in child-bearing women. M. Richelot then discussed the causes to which this condition was usually attributed—puerperal metritis, metritis, "the weight of the organ," relaxation of the tissues, mechanical causes such as a full bladder, constipation, and prolonged decubitus—and emphasised his disbelief in the prevalent theory that the retroversion was due to an infection. The most rational theory put forward was the slackening of the ligaments consequent on pregnancy; but he had often seen the condition present in young girls. He had found retroversion

THE FIFTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

Held at Lisbon, April 19th—April 26th, 1906.

THE SECTIONS.

MEDICINE.

Chorea considered as Cerebral Rheumatism.

Sir DYCE DUCKWORTH (London) read a communication treating of the above subject. He said that chorea (of Sydenham) was now regarded as a disease caused by an infective agency and not merely as the result of shock or fright occurring in persons of neurotic and unstable temperament. He pointed out that the peccant matter of rheumatism which is now looked upon as of microbic origin—diplococcus or streptococcus—is assuredly the most frequent if not the sole cause of the infection. No other microbic element than this diplococcus had been discovered in those cases of chorea which were believed to be unconnected with rheumatism and independent of rheumatic influence. The infecting agent appeared to be somewhat similar to, but distinct from, other varieties of streptococcus which mark the ordinary forms of pyæmia. Consequently chorea should be considered as a form of rheumatism involving the membranes and cortical structure of the brain and was, in fact, cerebral rheumatism. In the pathogeny of chorea there was a neurotic element which predisposed subjects to the manifestation of symptoms, among others, of rheumatism. Therefore chorea must be regarded as a neuro-humoral disorder.

Myositis Ossificans.

Dr. EDWARD WOLFENDEN COLLINS (Sydenham) read a paper in which he dealt with a solitary instance of the very rare, progressive, and incurable dyscrasia known as "myositis ossificans." He stated that this was the only case of this malady which had come under his personal observation during a practice extending over a considerable period. Less than a hundred in number of similar cases had been recorded by British, continental, and trans-Atlantic observers. The subject of this uncommon pathological condition described by Dr. Collins was a little girl, now eight years of age. About a year after her birth bony kernels resembling enlarged glands, for which they were at first mistaken, were noticed in the neck. During the past three years the rigid condition of the neck had gradually increased with extension of the bony formations to the shoulders, pectoral muscles, and back; and in the course of the past three months bony deposits had also become manifest at the back of each heel in proximity to the insertion of the tendo Achillis. The outward movements of the arm had become seriously crippled owing to the extensive deposits in the pectoral muscles, while the rigidity of the muscles of the neck and back rendered bending movements impossible. Her forearms and lower extremities had escaped so far. Her only complaint was at times of pain in the back. She had not suffered in general health and none of her relatives, near or distant, had been afflicted in a like manner. At the time of her birth the shortening of the big toes with deviation towards the middle line of the foot attracted attention. This remarkable congenital deformity, said Dr. Collins, wherein the big toe presents only one phalanx and that deviating outwards—a combination of micro-dactyle with hallux valgus—had been noticed in so many cases of myositis ossificans that it could hardly be regarded merely as a coincidence, and it might be added that a similar congenital deformity of the thumbs had been occasionally observed in cases of this disease. In summing up the information at our disposal concerning this strange form of degeneration it might be stated briefly that it commenced, as a rule, in childhood, owing to some constitutional proclivity to bony deposit. It was not of hereditary origin, as no instance was known of its occurrence in parent as well as in offspring or of its having affected more than one member of a family. Its pathological essence was the deposition of bony masses in the cellular tissue which binds the muscular fibres together, causing absorption of these fibres and taking their place. That the bony deposits consisted of true bone tissue had been clearly demonstrated whenever, after excision, their chemical and microscopical composition had been determined. Nothing was known of the first causation beyond the fact that in many instances injury had been either the apparent starting point or had aggravated the malady and that not infrequently it had followed exposure to cold or a chill, in this respect, as well as in the pains which accompanied it, showing an affinity with muscular rheumatism, and more especially in respect of its bony outgrowths with rheumatoid arthritis. Its course was essentially chronic and progressive, though not without periods of remission. It usually began in the muscles of the neck and back, whence it spread gradually to those of the shoulders, chest, and limbs to such a degree that the chest finally became an immoveable cuirass and voluntary movements of the limbs became impossible. The abdominal muscles, however, with the diaphragm and other vital muscles, enjoyed a singular immunity. Visceral and joint lesions were conspicuous by their absence and the general health remained unimpaired. Death was generally brought about by pulmonary complications, aggravated, if not induced, by the crippled movements of the chest walls, or by the sloughing of the tissues over prominent bony outgrowths with sequelæ of sepsis. Treatment had been found unavailing even to arrest the progress of the disease.

Successful Treatment of the Fulminating Form of Appendicitis simulating the Onset of a Severe Attack of Influenza or of Acute Pneumonia by Iron Acetate and Belladonna.

Mr. HERBERT J. ROBSON (Leeds) read a communication on the above subject, in which he pointed out that treatment of pneumonia by the regular administration of iron acetate and strychnine (in those cases in which the latter drug was called for) was indicated in cases of severe broncho-pneumonia occurring in infants or in children and in catarrhal and lobar pneumonia occurring in debilitated subjects. Two properly trained nurses should be available for night and day respectively, as the regular administration of strychnine by day and by night kept up the heart's action and the danger of heart failure at the crisis was very much lessened. Such treatment was called for, too, in that infectious, creeping, and spreading form of pneumonia following or accompanying influenza. By using these therapeutic measures the crisis was hastened and favourably modified, the virulence of the disease was lessened, and the complication of empyema seldom occurred. Even when bronchitis was present there seldom seemed any need to prescribe depressing drugs like ipecacuanha, as the iron acetate acted as a good expectorant. Mr. Robson stated that according to his view of the situation, referring particularly to the treatment of the fulminating form of appendicitis, the patient or a friend of the patient should first be told how matters stood so that the option of immediate operation might be given, as well as the option of consultation with an operating surgeon. An opiate should be given to relieve abdominal pain, extract of belladonna administered every three hours until physiological symptoms of belladonna were noticed, when its administration should be less frequent, and a mixture of solution of perchloride of iron 15 minims, solution of acetate of ammonia two drachms, with chloroform water in sufficient quantity should be given every three hours in water. Hot applications might be used to relieve headache and backache, derivatives of the coal-tar series being carefully avoided; warmth should be applied to the abdomen, while a rectal soap enema might be given to relieve constipation when present, purgatives, of course, being avoided. The patient should be put on a light nutritious diet and strict rest in a recumbent position should be enjoined and the temperature of the bedroom kept at 60° F. by night and by day. The administration of belladonna should be regarded as an important adjunct in the treatment, not only on account of its sedative action upon the intestines but also because of its anti-suppurative action, as pointed out by Christopher Heath, Ringer, and others.

OPHTHALMOLOGY.

Colour Contrasts and Astigmatism.

Dr. C. A. OLLIVER (Philadelphia) read a paper on this subject founded upon several hundred experiments made with the aid of, and at the suggestion of, Dr. S. Weir Mitchell. The subjects were intelligent ametropes of both known and unknown kinds and degrees of astigmatism. During the experimentation a distinct relationship between forget that the outpost station at the best was only a halting-place for the wounded on the way to the ambulance and that he had only to aim at preparing for them as easy and comfortable a journey as possible. The sick and wounded must also be sent away as soon as possible; only the dying should be retained at the outpost station. He summed up the duties of the medical officer in charge: (1) to send back to the ranks after suitable treatment men whose lesions were insignificant and who could continue to fight; (2) to apply the recognised dressing to simple wounds caused by rifle bullets of small calibre; (3) to arrest or to diminish profuse hæmorrhage by compression of the main artery at a distance from the wound when possible or by compression of the wound itself with an aseptic pad of wool soaked in very hot water; (4) to put up broken limbs in improvised splints; (5) to perform tracheotomy where the neck was wounded and imminent asphyxia threatened; (6) to give morphine hypodermically where pain was intense and ether injections or camphor oil to the wounded who were in want of energetic stimulation; (7) to have the water boiled, whether for cleansing the hands or for other purposes; (8) to protect from infection by means of a coating of collodion those parts of the skin where it was necessary to make an injection or an incision and also all wounds requiring a dressing; and (9) to send the wounded to the ambulance—in the first place, those who had hæmorrhage arrested by compression; secondly, those who urgently required any operation; and thirdly, those severely wounded whose wounds could not be properly attended to at the outpost station.

M. MANUEL GIÃO (Lisbon) read a paper on the

Organisation of the Military Medical Service at the Front.

He quoted approvingly the saying that "the success of the medical service depended upon its organisation." He was glad that the subject had been considered worthy of discussion at an International Congress; this could only result in improvement of the lot of the wounded at the front in war. In most armies the military medical service at the front consisted of three divisions, which might be broadly described as (1) the regimental service; (2) the ambulances; and (3) the hospitals. The first two divisions had always to be in readiness to follow the movements of the troops and to that end to get rid as soon as possible of their sick and wounded. Thus the outpost stations passed on patients to the ambulances and these in turn passed them on to the hospitals on the same or the following day. This method of organisation was open to criticism; it was incapable of being adapted to a sudden call on the battlefield. Gavoy had proposed the creation of a hospital providing vehicles for the transport of the wounded, thus relieving the ambulance and permitting it to come to the aid of the outpost stations. M. Gião had recently instituted a new organisation for the Portuguese army at the front which he briefly described: (1) preservation of the regimental service; (2) substitution of the ambulances and hospitals by medical formations of a uniform type; (3) collection of material for the transport of the sick and wounded in an independent division; and (4) creation of a new unit supplied with hospital material sufficient for the needs of these formations when they became stationary. These new formations were called *hôpitaux de sang*; the division for transport was called the transport column and insured the transport of the wounded on the battlefield; the new units or hospital columns carried all the stores necessary for the *hôpitaux de sang* when they required to become stationary for the treatment of severely wounded men. Each hospital and each column formed an independent unit from the administrative point of view. The hospitals did not relieve each other, they exchanged places in the marching columns. They were relieved by the service of the second line. The hospital was controlled by a medical officer, the transport column by a transport officer, and the hospital column by an administrative officer. The three units could be arranged according to the necessities of the service. The command of the party always reverted to the medical officer. To be turned to the best account the hospitals and the accessory columns ought to be placed under the immediate orders of the chief medical officer of the unit. M. Gião gave details as to the attending staff, the stores and the material required, and the respective duties of the regimental service, the transport column, the *hôpitaux de sang*, and the hospital column. He considered that each division should have six *hôpitaux de sang*, two transport columns, and four hospital columns.

FORENSIC MEDICINE.

The Procuring of Abortion.

Dr. STANLEY B. ATKINSON (London) read a paper dealing with the circumstances which justify an operation with a view to procuring abortion. After laying down as a necessary reason for such interference the strong probability that continued pregnancy would prove fatal to the prospective mother he proceeded to cite instances illustrating the principle thus enunciated, emphasising the duty of establishing beyond question the existence of the physical conditions relied upon.

Professor VAN DER VEER (Albany, U.S.A.) in a subsequent paper attributed the criminal procuration of abortion among the very poor to temptation arising out of their extreme poverty; among the middle classes to a desire to avoid the expense of a family, lest it should affect their social position; and in the wealthy classes to the desire to avoid the trouble of rearing children, coupled with the fact that money enabled these to obtain what they desired with a comparative degree of safety. He urged that it was the duty of a medical man called in as a consultant, if convinced that criminal abortion had been procured, to inform the proper authorities at once of the fact that it had taken place and insisted that in cases where there was evidence that a medical man, or a woman having medical skill to aid her, had procured abortion every step should be taken to bring about the punishment of the guilty person. He mentioned the increased safety attending the crime of procuring abortion in consequence of modern precautions to avoid sepsis but nevertheless he was of opinion that information disseminated as to the inevitable physical danger would do much to prevent women from running the risks involved, and also that duly imparted knowledge of the enormity of the crime might also serve as a deterrent.

Railway Surgery in America.

Dr. GEORGE CHAFFEE (Brooklyn) and Dr. CLARK BELL, LL.D. (New York), described the development in the United States of a class of surgeons devoting themselves to the study and treatment of accident cases occurring upon the extensive and growing railway systems of the country and gave particulars of the organisation of the railway surgeon's practice and of the work performed.

The Scientific Treatment of Social Offenders.

Dr. J. MOUNT FLEYER (New York) compared and contrasted the effects of "nature" and of "nurture" in the production and reformation of criminals. He was of opinion that where hereditary conditions pointed unmistakeably to the procreation of an offspring predestined to inherit criminal propensities "nature" would not be overcome by "nurture" and the criminal element would remain paramount in the character of the subject in spite of the efforts made to direct and to reform it. He discussed in detail the duty of the State in the restraint, education, and reformation of the degenerate.

Insanity in Prisons.

An interesting paper was read by Dr. PACTET, chief medical officer of the asylum of Villejuif, having for its subject the frequent occurrence of cases of mental disease in prisons without recognition and without proper treatment being accorded to those affected. The existence of insane prisoners subjected to the discipline imposed upon ordinary prisoners Dr. Pactet declared to be established by the unanimous testimony of prison governors, of medical alienists who had had the opportunity of forming opinions on the subject, and particularly by an inquiry which he himself had conducted, and in the course of which he had consulted experts in various countries. Some of these prisoners were insane when sentenced, others had since become affected. The exact proportion which they bore to the sane inmates of the same institutions could not be established owing to the lack of scientifically compiled data, but available statistics from abroad seemed to point to 5 or 6 per cent. at least as a probable proportion, while according to the opinion of several prison governors in France about 15 per cent. of their charges might advisedly be submitted to examination as to their mental condition. In the existing state of affairs, however, the presence of insanity remained undetected even after a long period of imprisonment had been undergone, and in an instance referred to a man condemed to five years' confinement for homicide completed his sentence as an ordinary prisoner when he should have been in a lunatic asylum.

associated with moveable kidney, enteroptosis, and hernia; it occurred, in his opinion, in those with a neuro-arthritic diathesis, whose chief symptom was a tendency to a loosening or "want of tone" of all their fibrous tissues. Research conducted on this line would, he felt certain, explain the uterine condition. The clinical symptoms were then fully narrated in order of evolution and the chaos of prevalent teaching on the subject was reduced to the simple element of congestion. M. Richelot then passed to the treatment. Five years previously he had recommended an operation (first conceived by Doléris) which had at the time provoked adverse criticism. It consisted in making a short median laparotomy, seizing the round ligaments at a short distance from the uterine cornua, where they were firm and thick, bringing them up to the inferior angle of the wound, and fixing them firmly with two or three catgut stitches. The crux lay in the method of fixation; the ligaments must be inserted into the thickness of the muscular aponeurotic layer; if they were sutured only to the peritoneum the fixation would be useless. Doléris had added a modification to this but the ease and simplicity of the above recommended it. Alexander's operation was criticised and the operations in vogue at former times were passed in review. Between October, 1899, and September, 1905, M. Richelot had performed the operation recommended above on no fewer than 80 patients. In 18 of these 80 slight traces of peritoneal irritation had been detected at the time of operation; in 62 the peritoneum had been normal. The uterus in all cases had been mobile; the cases had belonged to the group of primary retroversions. Of these 80 cases only *one* had *not* been relieved, 25 had been lost sight of after apparent cure, 15 had been operated upon so recently that it was unfair to count them as cured, and 39 remained quite cured. By "cured" he meant absence of pain and fatigue after exercise, a resumption of social and other duties fulfilled by healthy women. Three of the patients had become mothers and had not had any return of uterine *symptoms*. M. Richelot then narrated in detail four cases which served as examples of the way in which the operation transformed a patient from a weary, suffering invalid to an active and a useful member of her household.

Dr. ALFREDO DA COSTA (Lisbon) read a paper on

The Indications for, and the Technique of, Cæsarean Section

The various operative methods employed in cases with contracted pelves were first reviewed. 1. Symphysiotomy was easily performed, but very dangerous complications were liable to accompany or to follow it, such as involvement of the urethra, rupture of the vagina and vulva, and persistent pain at the pubes, and the sacro iliac joints. 2. Ischio-pubiotomy was originated and once successfully performed by Farabeuf; this operation, however, had been abandoned by its inventor. 3. Hebotomy, or pubiotomy, Gigli's operation, had in Dr. da Costa's opinion a future before it on account of the simplicity of its performance. It was, in fact, a perfected symphysiotomy, inasmuch as it had none of the dangerous drawbacks of symphysiotomy. 4. Embryotomy was not performed nowadays. Cæsarean section was preferable to all these methods, excepting when the membranes had been ruptured for some time or the uterus was the site of any infection which might pass into the general circulation The *most appropriate time* for the performance of the operation was at the commencement of labour; he disapproved of its performance before labour started, because every prematurely born infant started life at a disadvantage. In the choice of the uterine incision the surgeon must be guided by the special circumstances of each case. The longitudinal anterior median incision *was usually best* Before the uterus was opened, and *certainly before the extraction of* the child, an assistant should place two fingers in the vagina ready to push up the presenting part when requested by the operator. All forms of uterine suture were good if, *in addition* to strength, they had perfect adaptation of the incised edges and were impermeable to the passage of fluid from the uterus. Extra-peritoneal Cæsarean operations had not much clinical value. Dr. da Costa then described at length an original and ingenious method of suturing the abdominal wall; the scar was not only firmer but the skin cicatrix was narrower and less disfiguring than that produced by the ordinary method. The peritoneum, the muscular aponeurosis, and the skin were separately sewn up with silk, the two ends of each thread being tightly wound round a button specially devised for the purpose and fixed with collodion. When the wound was healed the buttons and the *thread were easily removed*, leaving a narrow linear scar in the middle line.

Dr. TH. TUFFIER (Paris) and Dr. DE ROUVILLE (Montpellier) communicated a paper on

The Treatment of Uterine Fibroids.

The general indications regarding operative interference had not altered since 1899 and might be summed up thus (1) rapidly growing fibroids should be removed; (2) stationary fibroids should be left alone; and (3) fibroids compressing the bladder, intestines, or ureters, or causing *profuse* hæmorrhage, should be got rid of. Albuminuria and cachexia were usually mentioned as contra indicating an operation. In the presence of albuminuria the urine was carefully examined as to the power of excretion of methylene blue and salts by the kidney, and when the results proved satisfactory operation was recommended. Anæmia and mild septicæmia were indications for operation. Medical treatment by rest, hot injections, and electricity was discuss The best results were obtained by water containi chloride of sodium; the waters of Balaruc, Salies, a Brucoutz appeared to diminish the congestion, and he the volume of the tumours, and were to be recommended cases where operation was inadvisable. Palliative surge consisted of curetting, ligature of the uterine arteries, a removal of the ovaries. The last named was the most effic cious when practicable. Curative surgery consisted of hyst ectomy and enucleation and when possible enucleation w preferable. The indications for vaginal and transvagin enucleation were reviewed and the indications for hyst ectomy considered at length. The mortality of abdomin enucleation was 2 75 per cent. and relapses were rare. Wh considering the methods of procedure for hysterectomy note of warning was sounded as to the danger of the Tre delenburg position for stout patients and those whose c culation was feeble. Unless the cervix was involved it w preferable to leave it *in situ;* there were few indications f total hysterectomy. The treatment of fibroids complicat by pregnancy was fully discussed.

MILITARY MEDICINE.

Secondary Disinfection of Infected Gunshot Wounds.

Colonel NICHOLAS SENN, M.D. (Chicago), communicated paper on the above subject. Dr. Senn is an authorit of some note with regard to gunshot wounds, he havin had a considerable experience of such injuries durin the Spanish-American war. Dr. Senn's worldwide rep tation as a surgeon also added weight to his testimon He pointed out that as the fate of the wounded depende largely on the thoroughness with which first aid wa rendered, the military surgeons must make ample pr vision in time of peace in order to secure efficiency o this service in time of war. Attention was drawn t the fact that first-aid dressing should combine sim plicity with safety against infection after injury. Th point was dwelt upon that first aid must have i view the treatment of shock, hæmorrhage, dressing o wound, and immobilisation of the injured part. Dr. Sen laid down as an invariable rule in the treatment of gunsho wounds that the probing of such wounds must be prohibited Furthermore, he insisted that in no circumstances shoul attempts be made to extract bullets until this could b done in a well-equipped hospital under the strictest asepti precautions, and then only in cases where an operation o this nature was clearly indicated by the fact that the bulle could be felt through the intact skin or its exact locatio had been determined by the employment of the x rays. The conclusions arrived at were as follows: duties of the surgeon at the first dressing, inspection of first-aid dressings and more efficient immobilisation of the injured part. Immediate duties · emergency operation, as definitive arrest of hæmorrhage, amputations, and laparotomy.

Lieutenant-Colonel JOSE BARBOSA LEÃO (Lisbon) read a paper on

Surgery in War at the First aid Stations at the Front.

He reviewed the conditions under which these stations had to work and discussed the methods of dealing with the wounded on the field of establish that the *rusting of iron only takes place in the presence* of carbonic acid. Professor Wyndham Dunstan showed some interesting minerals from Ceylon and also some from Canada, while the exhibit included some specimens illustrating an investigation on certain cyanogenetic plants. Sir Oliver Lodge and Dr. Alexander Muirhead exhibited a portable set of wireless telegraphy apparatus for military field purposes available for communication across country for distances up to 50 miles or 150 miles over sea. Professor John Milne exhibited seismograms of three recent earthquakes, including that which occurred at San Francisco. The Royal Observatory, Edinburgh, exhibited similar records. Mr. E. G. Rivers explained the construction and working of a new electric heater, in which a large heating surface kept at a moderate temperature is employed, silicated carbon with a terra-cotta base forming an "element." The apparatus, it is said, will warm a room 12 feet by 12 and 10 feet high at a cost of a little over 1*d*. an hour with the current at 1½*d* per unit.

Demonstrations in the meeting room by means of the electric lantern were given by Mr. G. W. Lamplugh, who exhibited some very fine photographs of the Batoka Gorge of the Zambesi river, while Professor Sylvanus P. Thompson gave an admirably illustrated account of the electric production of nitrates from the atmosphere. The method consists in converting the nitrogen of the air into nitrous vapours which takes place by passing air through "a roaring disc of flames" or electric discharges about six feet in diameter. The nitrous fumes are absorbed in water and in quicklime. The product is used for agriculture and the power in the particular instance cited is furnished by waterfalls in Norway. One kilowatt, Professor Thompson states, may be taken as able to produce 500 kilogrammes of nitrates at least per annum.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE.—At the convocation held on April 28th the following degrees and diplomas were conferred:—

Doctor in Medicine.—Charles Harold Clarke, M.B., B.S. *Durh.*; Ida Emilie Fox, M.B., B.S. Durh.; Harold Linton Heslop, M.B., B.S. Durh.; Herbert Lovis Noel Cox, M.B. Durh.; Thomas Young Simpson, M.B., B.S. Durh., and James Bowden Waters, M.B., B.S. Durh.

Doctor in Medicine for Practitioners of 15 years' standing.—Bennet Harvey Andrew, M.R.C.S., L.R.C.P., L.S.A.; Henry Buxton, F.R.C.S. Edin., L.R.C.P., L.F.P.S.G.; Ernest Carrick Freeman, M.R.C.S., L.R.C.P., D.P.H., John Frederick Nall, F.R.C.S. Eng.; Richard Reginald Sleman, M.A., L.S.A.; James Pixton Walker, M.R.C.S., L.R.C.P.; and Alfred Whalley Waller, M.R.C.S., L.R.C.P.

Bachelor in Medicine (M.B.) and Bachelor in Surgery (B.S.).—William Frederick Cheese, M.R.C.S., L.R.C.P., St. Bartholomew's Hospital; James Henry Cooke, B.Litt., Hamilton Drummond, Horsley Drummond, and Wilfrid Fairclough, College of Medicine, Newcastle-upon-Tyne; Archibald Finlay, London Hospital, John Galloway, L.R.C.P. & S. Edin., L.F.P.S.G., College of Medicine, Newcastle-upon-Tyne; Sampson George Victor Harris, M.R.C.S., L.R.C.P., D.P.H., Charing Cross Hospital; Arthur Beresford Jones, John Cuthbert Pearce, A.Sc., Robert Blackett Reed, William Seymour, Frederick James Strachan, and Edward Tate, College of Medicine, Newcastle-upon-Tyne; Arthur John Turner, London Hospital; and Robert Joseph Weldner and Robert Joseph Willan, College of Medicine, Newcastle-upon-Tyne.

Bachelor in Medicine (M.B.).—Frank Tomlinson Simpson, College of Medicine, Newcastle upon-Tyne.

Bachelor in Surgery (B.S.)—Sidney Herbert Hawley, M.D., B.Sc., D.P.H., Birmingham University.

Bachelor in Hygiene (B.Hy.).—John Wilson Howard Morrison, M.B., B.S. Durh.; Henry Renny, M.D., B.S., D.P.H. Durh., and Herbert James Slade, M.B., B.S. *Durh.*, M.R.C.S., L.R.C.P.

Diploma in Public Health (D.P.H.).—James Alexander Mitchell, M.B., Ch.B. Glasg., John Wilson Howard Morrison, M.B., B.S. Durh.; and Herbert James Slade, M.B., B.S. Durh., M.R.C.S., L.R.C.P.

UNIVERSITY OF OXFORD.—The degree of D.M. has been conferred on Cyril Ogle, M.A., M.B., B.Ch., Trinity College, F.R.C.P.—The electors will proceed to the election of a Sibthorpian Professor of Rural Economy on Saturday, June 9th. Candidates are requested to send in their applications on or before May 19th to the registrar of the University, from whom all particulars may be obtained. Among the conditions is the following: "The Sibthorpian Professor of Rural Economy shall lecture and give instruction on the scientific principles of Agriculture and Forestry, including the Pathology of Plants.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—A meeting of the Fellows will be held on Saturday, June 9th, at 1 o'clock, to receive the annual report of the council. A meeting will also be held on Monday the 11th, at 1 o'clock, pursuant to the provisions of the charters, to elect a president, vice president, council, and honorary secretary of the College for the ensuing year. Fellows who may desire to have their names printed on the list of candidates for office should signify their wish by letter to the Registrar at the College on or before Wednesday, May 30th.—At a meeting of the President, Vice-President, and Council held on May 1st the following examiners were elected. Court "A," for Conjoint Licence, Diploma in Public Health, and preliminary. Anatomy: Mr. Alexander Fraser and Dr. Bertram C. A. Windle. Surgery: Mr. Alexander Blaney, Mr. F. Conway-Dwyer, Mr. John Dundon, and Mr. Richard Lane-Joynt. Pathology and Bacteriology: Mr. Arthur Hamilton White. Midwifery and Gynæcology: Mr. Frederick W. Kidd. Biology: Mr. John J. Burgess. Ophthalmology: Mr. Arthur H. Benson and Mr. Herbert C. Mooney. Sanitary Law and Vital Statistics: Mr. Edward Francis Stephenson. Languages: Mr. L. J. Woodrooffe. Mathematics, Physics, Dictation, and English Essay: Mr. J. W. Tristram. Court "B," Fellowship, Licence in Surgery (for registered practitioners), Licence in Midwifery (for registered practitioners), and Licence in Dental Surgery. Anatomy: Mr. Patrick Joseph Fagan and Mr. Alexander Fraser. Surgery: Mr. Alexander Blaney, Mr. F. Conway-Dwyer, Mr. Thomas E. Gordon, and Mr. Richard Lane Joynt. Pathology and Bacteriology: Mr. Leveson Gower Gunn and Mr. Arthur Hamilton White. Midwifery and Gynæcology: Mr. Frederick W. Kidd. Chemistry and Physics: Mr. Edwin Lapper and Mr. Robert J. Montgomery. Dental Surgery and Pathology: Mr. George M. P. Murray and Mr. William G. Story. Mechanical Dentistry: Mr. Kevin E. O'Duffy and Mr. Daniel L. Rogers.

THE ANNUAL DINNER OF THE ROYAL SANITARY INSTITUTE.—The annual dinner of the Royal Sanitary Institute was held at the Langham Hotel, Portland-place, London, W., on May 9th, the Duke of Northumberland, K.G., the President of the institute, being in the chair. Among those present were Colonel J. Lane Notter, R.A.M.C. (*retired*) (the chairman of the council), Sir Francis Sharp Powell, Bart., M.P., and Sir Alexander Binnie (vice-presidents of the Institute), Sir Lauder Brunton, F.R.S., Sir Shirley F. Murphy, Surgeon-General A. H. Keogh (Director-General of the Army Medical Service), Sir R. Melvill Beachcroft (chairman of the Metropolitan Water Board), the Rev. Canon Barker, and Mr. Evan Spicer, J.P. (the chairman of the London County Council). After the usual loyal toasts had been given from the chair by the President, Sir Lauder Brunton proposed "The Navy, Army, and Auxiliary Forces," and referred to the work of Edward Parkes and Colonel Lane Notter. The toast was responded to by Surgeon-General Keogh, who insisted that the first duty of the medical service of the Army was the prevention of disease. He regarded the fact that 40,000 cases of enteric fever occurred in the late South African war as disgraceful and further dealt with the question of the water-supply to the army in war. It was impracticable to boil all the water used by the troops but he regarded the water problem as on the eve of solution by the application of the Slack and Brownlow filter to the service watercart. The toast of "The Houses of Parliament" was given in a witty speech by Sir Melvill Beachcroft and responded to by Sir Francis Sharp Powell, who paid a tribute to the earnest work of the Labour Members in the new Parliament. The Duke of Northumberland in proposing the toast of "The Royal Sanitary Institute" spoke of the cold douche which had been applied to the question of vaccination and of his personal disappointment at the attitude of the authorities towards revaccination which he regarded as a necessity. He also referred to the growing interest in tropical medicine and spoke in eulogistic terms of the work of the schools of tropical medicine in London and Liverpool. The toast was responded to by Colonel Lane Notter. "The Health of the Visitors" was proposed by Sir Alexander Binnie, President of the Institute of Civil Engineers. It was responded to by Mr. Evan Spicer, who referred in grateful terms to the assistance afforded by the institute to the London County Council in sanitary matters. The proceeding

This, in fact, was what would naturally occur so long as the insanity of the convict was not such as would prevent altogether his compliance with the discipline of the prison. Such a state of affairs violated the principle with which all would now agree, that the proper place for the detention of a person mentally defective was an asylum, and it had been responsible in one case for a dangerous attempt upon the life of a prison warder committed by an insane prisoner upon the very day of his release from gaol. In discussing remedies Dr. Pactet pointed out that if the medical officers of prisons were qualified by training to detect and to deal with mental disease the evil would be considerably diminished, but he was of opinion that in order to reduce it effectively it would be necessary to follow the example set by Belgium and to establish a system of thoroughly qualified medical commissioners specially empowered to remove and to place in suitable asylums prisoners found to require the treatment accorded to the mentally defective. He described an attempt in this direction, consisting in an inquiry due to the initiative of Dr. Henri Colin, his colleague at Villejuif, but in spite of official support, enabling them to examine prisoners whose records led them to suspect insanity, opposition and resistance had arisen which had crippled the efficacy of the work done. The establishment by law of a special service for the mental examination of prisoners was, he urged, a reform in which Belgium had set the example and towards which the favourable opinion of the Congress might materially contribute.

Other Papers.

Addresses relating to, and arising out of, a charge of murder by the inhalation of chloroform in the United States were also read in this section and Dr. THEODORE SCHROEDER (New York) contributed a paper on the question, How Should "Obscene" be Defined in Legal and Medical Literature?

COLONIAL MEDICINE.

Dr. F. W. MOTT (London) read a paper upon

Histological Observations in Sleeping Sickness and other Trypanosome Infections

in which he came to the following conclusions which were supported by experimental evidence:—1. Sleeping sickness was a chronic disease caused by the trypanosoma Gambiense conveyed by a biting fly, the glossina palpalis. 2. Every case of sleeping sickness—30 in all—which he had examined (including the European case recorded by Sir Patrick Manson) had presented the same characteristic meningo-encephalitis which he described in 1898. 3. There was a parallelism between the intensity of the lethargy, the chronicity of the disease, and the characteristic histological changes in the central nervous system. 4. The disease was characterised by a chronic polyadenitis which was followed by a chronic inflammatory change in the lymphatics of the brain and spinal cord. 5. This chronic inflammatory change was manifested by a proliferation and overgrowth of the neuroglia cells, especially of those which were related to the perivascular lymph spaces, also a proliferation and accumulation of lymphocytes in the dense neuroglial meshwork. The lymphocytes might in chronic cases form plasma cells, as they did in the chronic inflamed lymphatic glands. Various other cells were met with in less numbers, some being the result of degenerative changes, others were endothelial with phagocytic activity. 6. Examination of the fresh juice of the glands obtained during life by puncture proved conclusively that the trypanosomes were the cause of their enlargement and of the chronic inflammatory changes met with in them. The microscopic evidence of the existence of trypanosomes in sections of the lymphatic glands was not more satisfactory than the evidence of their existence in the perivascular and meningeal infiltration of the nervous tissues. Chromatin particles, some of which might be micro-nuclei and macro-nuclei, could be seen as well in one as in the other and only very rarely could a trypanosome be found. 7. All cases of sleeping sickness had trypanosomes in the cerebro-spinal fluid at some time or other and it was probable that the entrance of the trypanosomes into this fluid marked the onset of, and slowly caused, the chronic inflammatory changes in the lymphatic system of the central nervous system. The alternative hypothesis was that the trypanosomes by multiplying in the lymphatic glands produced a toxin which was absorbed by the lymphatics proceeding along the vessels and nerves to the cerebro-spinal axis, the route being especially from the cervical glands by the lymphatics of the large vessels and nerves entering the base of the skull. 8. The infrequency with which trypanosomes could be demonstrated in the blood and infiltrations of sections of sleeping sickness tissues might also be accounted for as follows: (*a*) the trypanosoma Gambiense was not found without careful search in blood films even of severe cases; and (*b*) after death in 80 per cent. of the 30 cases which he had examined secondary or terminal microbial infection (generally by the diplococcus or diplostreptococcus) was found, and as the culture experiments of Novy and McNeal show, micro-organisms were inimical to the growth of trypanosomes in the blood and infiltrations. The case in which he found most evidence of trypanosomes in sections of the tissues was a chronic case uncomplicated by microbial infection. There was evidence to show that diplococcal invasion might be followed by inability to find the trypanosomes in blood films—e.g., the European case.

THE ROYAL SOCIETY CONVERSAZIONE.

THE Right Honourable the Lord Rayleigh, O.M., M.A., D.C.L., President of the Royal Society, received a distinguished number of guests on the occasion of the first annual conversazione which was held at Burlington House on May 9th. The exhibits were more than usually numerous and wider in character than has been the case for some years and it did not seem to matter what particular field of science the visitor may have been interested in he was sure to find some illustration touching on his own study.

On the whole the application of the microscope to scientific research was the principal feature of the exhibition. It would not be an exaggeration to say that there were hundreds of microscopes in use. To begin with, Mr. J. E. S. Moore and Mr. C. E. Walker showed microscopic slides exemplifying recent researches in cell division. The preparations showed (1) leucocytes lying in cytoplasm in the early stage of cancer; and (2) first maiotic (heterotype) division in cancer of the breast, the division figures in this form of cancer being supposed to be rare. (These were products of the joint research with Professor Farmer.) There were also specimens showing characteristic permanent forms in chromosomes of first maiotic (heterotype) division, pluri-polar mitoses and amitoses in bone marrow, division figures in germinal area of lymphatic gland, and cells destined to become foot cells in the testis of embryo guinea-pig. Close by were some photomicrographs taken by Léon Foucault in 1844 of blood, milk, and crystals by Daguerré's method. The importance of the microscope in the examination of iron and steel also was admirably illustrated in the photomicrographs placed at the disposal of the Royal Society by the director of the National Physical Laboratory. Professor W. F. Barrett showed an "entoptiscope," an instrument which enables anyone to observe, to delineate, and to measure an obscurity, however minute, within the path of the rays in the eyeball. Next to the microscope the application of photography to astronomy formed a very interesting series of exhibits. The photographs of the solar corona shown by the Rev. A. L. Cortie and the Astronomer Royal were marvellous. They were taken during the total solar eclipse of August 30th, 1905. There were two interesting demonstrations of spectroscopic study. Sir William Crookes showed many photographs illustrating the ultra-violet spectra of metals while Dr. W. Marshall Watts exhibited a binocular spectroscope which gives very beautiful results. Sir James Dewar, F.R.S., exhibited a number of metallic jacketted vacuum vessels filled with liquid air. Next to this exhibit Mr. C. V. Boyes, F.R.S., demonstrated the use of a gas calorimeter which is used for determining the heating value of illuminating gas. Since the introduction of incandescent gas lighting this test has become more important than the measurement of illuminating power. Messrs. Wallach Bros. exhibited the rescue apparatus used in the appalling mine disaster at Courrières. Amongst the exhibits also was a "first-aid" case for use in poisoning by carbonic oxide and other gases. Dr. G. T. Moody exhibited specimens illustrating the indifference of oxygen towards iron in the presence of water and the effect of the admission of carbonic acid. The experiment seems to medical officers. Medical officers have been dismissed from their appointments for causes other than professional neglect or incompetence, in some cases from religious, political, or personal spleen, or from medical officers refusing to comply with orders which were quite outwith their duties as servants of the parish council. Compliance with some of the orders would have brought the medical officer under the ban of the General Medical Council, rendering him liable to be censured or even struck off the Medical Register. A large number of medical officers have thrown up their appointments in disgust owing to the petty annoyances to which they have been subjected, with the result that certain parish councils are in the market for new medical officers every few months, a condition of matters which is very detrimental from a public point of view, so far as the well-being of the inhabitants of those parishes are concerned. For some years this association has been urging the Local Government Board to promote legislation of such a character as would remove the grievances to which the Poor-law medical service are subject, on the following points:—1. An appeal to the Local Government Board in cases of unjust dismissal. 2. The right to order invalid diet to sick paupers without the right of veto on the part of inspectors of poor 3 The granting of power to parish councils to the use of [illegible] funds for building suitable dwelling houses for medical officers in places where such are required. 4. The granting of a suitable annual holiday at the expense of the parish council for medical officers in parishes where the greater part of the income is derived from the official salary. 5 The granting of a uniform fee of 21s for each case of lunacy. 6. The granting of a suitable fee for midwifery, fractures, dislocations, or other special cases The Departmental Committee of the Local Government Board, which held a most exhaustive inquiry into the medical relief of the poor, have recommended that the first three of our claims ought to be granted but have made no recommendation as to the last three claims. We understand a Bill has been drafted and only awaits a suitable opportunity to be brought before Parliament and passed into law. If such a Bill were passed into law we believe the Poor-law medical service would be contented Much against the wish of our association we have been compelled to warn applicants against accepting parish council appointments where the parish council have dismissed or treated their medical officers in an unjust manner. This course of action has been beneficial Almost no dismissals have taken place during the last two or three years We do not mean to claim that in no case has a parish council dismissed its medical officer without just cause or found fault with him for neglect of his professional duties Just causes for dismissal or censure must occur now and then, particularly when you consider that high-class young medical men do not now apply for vacant appointments in the Highlands and islands, the more obnoxious of the parish councils only getting the 'flotsam and jetsam' of the profession to become their servants." The Secretary for Scotland was very sympathetic in his reply and he undertook, whilst not specifically coming under any pledge, to consult with the authorities of his department on the complaints made.

HOUSE OF LORDS.

TUESDAY, MAY 8TH.

Poisons and Pharmacy Bill.

The Standing Committee of the House of Lords on Tuesday, May 8th, considered this Bill, the object of which is to amend the law, as to the sale of poisons and as to the Pharmacy Acts Viscount CROSS presided and the Earl of CREWE was in charge of the Bill on behalf of the Government.

The following new sub-section to Clause 3 was, on the motion of the Earl of CREWE, added to the Bill —

"The provisions of Section 16 of the Pharmacy Act, 1868, which enable the executor, administrator, or trustee of the estate of a deceased, pharmaceutical chemist or chemist and druggist to continue his business so long as such business is *bonâ fide* conducted by a duly qualified assistant, shall be construed as enabling such executor, administrator, or trustee to carry on the business, if and so long only, as in every premises where the business is carried on the business is *bonâ fide* conducted by a duly registered pharmaceutical chemist or chemist and druggist, as the case may be, and the name of the person by whom the business is so conducted in any premises is conspicuously exhibited in the premises."

Clause 4 of the Bill deals with the application of the Pharmacy Acts to companies and provides that companies who sell poisons and drugs must employ registered pharmaceutical chemists at all their premises where such business is carried on and must display the name of the registered chemist.

On this clause,

The Earl of CREWE moved several amendments, the object of which was to provide that the clause should apply to any body corporate whether a company registered under the Companies Acts or not.

Lord BELPER stated the opinion that the provision as to displaying the names of the chemists would cause a good deal of trouble, and he suggested that something should be done to obviate that.

The Earl of CREWE recognised that the point was of some importance, and he preferred to deal with it in the whole House rather than in this committee.

The amendment was adopted, as was also another moved by the Earl of CREWE, providing that in Scotland anything which under Clause 4 would be an offence if committed by a body corporate should be an offence if committed by a firm or partnership.

Lord LAWRENCE at some length complained that Ireland was excluded from the operation of the Bill.

The CHAIRMAN said that that was hardly a point for the Standing Committee It should be brought up in the House itself.

The Earl of CREWE said he might be allowed to explain that originally Ireland was included in the Bill. That, however, had been strongly objected to in various quarters on the ground that the case of Ireland had not been heard at the preliminary inquiry before the Bill was drafted

The Bill was then ordered to be reported to the House.

HOUSE OF COMMONS.

WEDNESDAY, MAY 2ND.

No Suitable Candidate.

Mr. SLOAN asked the Postmaster General whether arrangements would be made and when for the appointment of an official medical officer in connexion with the Downpatrick Post Office.—Mr. SYDNEY BUXTON replied: Up to the present a suitable candidate for the post in question has not been forthcoming.

Fruit Growing on Sewage Farms.

Mr. H. H. MARKS asked the representative of the President of the Board of Agriculture whether any action had been taken, or was contemplated, with reference to the recommendation of the departmental committee on the fruit industry that an inquiry should be instituted into the alleged practice of growing fruit on sewage farms and the effect of such a practice on the public health.—Sir E. STRACHEY replied. We have been in communication with the Local Government Board on this subject and we are informed that no instance of disease attributed to fruit grown on sewage farms is known in the Medical Department of the Board The information in the possession of the Board indicates that fruit is seldom grown on sewage farms in this country and there is no confirmation of the suggestion that injury to health is caused by fruit so grown.

Vaccination of Teachers.

Mr RAMSAY MACDONALD asked the President of the Board of Education whether he could allow local education authorities to use their discretion regarding the vaccination of teachers.—Mr BIRRELL answered: I am proposing to insert in the Board's regulations a provision under which vaccination will not, so far as the Board is concerned, be required of any intending teacher who may state to the Board when applying for recognition that he has conscientious objections to being vaccinated. It will rest with the local authority to decide in each case whether they shall employ such a teacher. The Board will keep a record of any teachers who have not been vaccinated. —Mr. ARNOLD-FORSTER asked whether a similar discretion existed in other civilised countries in the world.—Mr BIRRELL replied: I am not a judge of civilisation

THURSDAY, MAY 3RD.

Dangers of Celluloid Articles

Mr T. R BETHELL asked the Secretary of State for the Home Department whether his attention had been drawn to accidents arising from the use of celluloid hair combs; and whether, having regard to the inflammable nature of this material, he would consider the advisability of introducing legislation to secure the marking of these articles in such a way that the public might know the danger to which they were exposed by their use —Mr. GLADSTONE answered: I am aware that a certain number of accidents have arisen from this cause, especially when impure celluloid is used. The question of putting marks upon materials of all sorts that are likely to be dangerous is a very wide one and I do not see my way to deal specially with celluloid but I hope the question will call attention to the possible danger of these articles and will put the public on their guard.

Pathogenic Bacteria in London Water.

Mr B. S STRAUS asked the President of the Local Government Board whether, with the view of improving the London water-supplies, he would consider the advisability of compelling, by legislation or otherwise the use of the process now in existence which was capable of dealing satisfactorily with contaminated water by completely destroying all pathogenic bacteria remaining in the supply after sand filtration.—Mr. JOHN BURNS answered I am not sure what is the particular process to which my honourable friend refers. The Metropolitan Water Board has before it the question of the research work to be undertaken with a view to determining whether the present system of purification of the London water cannot be still further improved and every practicable means of obtaining the best results will no doubt be thoroughly investigated The matter does not appear to me to be one for compulsory action by legislation or otherwise at the present time.

Inoculation against Enteric Fever.

Mr. EUGENE WASON asked the Secretary of State for War whether he had yet received the report of the committee appointed to consider the question as to the value of inoculation against enteric fever, and, if so, would he lay it upon the table of the House?—Mr. HALDANE replied: The final report of the antityphoid inoculation committee has not yet been received. An interim report has, however, been received and the recommendation contained therein, that the practice of voluntary inoculation against enteric fever should be resumed, has been approved by the Army Council. The voluntary inoculation of men proceeding abroad is now being carried out and arrangements are being made for those now serving in India. I will lay this report on the table.

FRIDAY, MAY 4TH.

Malarial Fever.

Major SEELY asked the Under Secretary of State for the Colonies whether he could grant a return showing the measures taken in the Crown Colonies and Protectorates to eradicate malarial fever and the results as shown by the health statistics of the inhabitants.—Mr CHURCHILL answered: The honourable Member's wish has been noted and the Secretary of State is instructing the advisory board for the Tropical Disease Research Fund to consider how it can best be met.

MONDAY, MAY 7th.

Registrars and Deaths.

Mr. CHARLES ROBERTS asked the President of the Local Government Board whether any order was issued in [illegible] prohibiting the registrars concluded with the toast of "The Chairman," proposed by Colonel Lane Notter.

UNIVERSITY OF CAMBRIDGE.—Mr. F. Gayner, M.B., B.C., has been elected to a Research Scholarship in connexion with the committee for the Study of Special Diseases.

THE BOLINGBROKE HOSPITAL.—The Princess Royal, who was accompanied by the Duke of Fife, visited Wandsworth on May 5th to lay the foundation-stone of the new buildings of the Bolingbroke Hospital. On their arrival the Princess Royal and the Duke of Fife were received by Canon Erskine Clarke, chairman of the board of governors; Mr. Everard G. Thorne, vice-chairman; Dr. H. Campbell Thomson (physician), Mr. D'Arcy Power (senior surgeon), Mr. Gerald S. Hughes (medical superintendent), and the reception committee. The ceremony, which was a brief one, was preceded by prayers said by the Bishop of Kingston. The Princess Royal laid the stone with the usual formalities, being assisted in doing so by the architects, Mr. K. D. Young and Mr. Henry Hall. After the stone-laying the Princess received a number of purses. At the close of the ceremony the Princess paid a visit to the wards of the hospital. She talked graciously to many of the patients and in the children's ward she distributed to the little patients roses from the bouquet which had been presented to her by Miss Russell, the matron.

QUEEN VICTORIA'S JUBILEE INSTITUTE FOR NURSES.—In the report for 1905 submitted to Her Majesty by the council of Queen Victoria's Jubilee Institute for Nurses it appears that the council was obliged last year, in order to meet the necessary expenditure, to withdraw £1600 from capital. But the special committee initiated by Queen Alexandra and organised by Lady Cadogan will, it is hoped, be able to make good the deficiency. The analysis of expenditure shows that nearly half the income is devoted to the training of nurses and another quarter to inspection and superintendence in order to maintain the standard of nursing work throughout the country. The institute's sphere of work is extending year by year and the Queen's nurses have in their hands an unlimited influence for good and it is now evident that they are in fact a social power for the improvement and education of those among whom they work. The Queen's nurses have been the pioneers in the work of nursing in the elementary schools which is now being developed very rapidly and has come to be recognised as a necessary factor in the success of any medical inspection of school children. The total number of associations now affiliated to the institute employing Queen's nurses is 694 and the number of Queen's nurses employed on Jan. 1st was 1313. Both figures show a considerable increase on the previous year.

DONATIONS AND BEQUESTS.—The Drapers' Company has sent a cheque for £10,000 to the fund for the removal of King's College Hospital to South London. The Skinners' Company has sent £250, being the first instalment of its promised donation of £500; and the Leathersellers' Company has contributed 100 guineas.—Among the donations received by the committee of the General Lying-in Hospital, York-road, Lambeth, towards the special fund for enlargement to meet the requirements of King Edward's Hospital Fund are the following: Lord Lister, president of the hospital, £100; Lord Iveagh, £50; collected by nurses and friends, £58.—By his will Mr. George Vye of Ramsgate has bequeathed £1000 to the Seamen's Infirmary and General Hospital, Ramsgate, and £250 to the Ramsgate Dispensary.—By the will of Mrs. L. B. E. Waterman £1500 are bequeathed to the Royal United Hospital, Bath, to endow a bed and a cot in memory of "General Edmund Frederick Waterman and Louisa Butler Eliza Waterman, his wife."—The late Mr. Charles Edwin Trimmer of Farnham has bequeathed £3000 to Trimmer's Cottage Hospital, Farnham, and £300 to the Royal County Hospital, Guildford.—The late Mr. J. Oliff has bequeathed £600 to the funds of the Bristol Royal Infirmary.—Under the will of Mrs. Mary Seaton, of Chorlton-on-Medlock, Manchester, £1000 are bequeathed to the Northern Counties' Home and Hospital for Incurables; £500 to endow a cot for crippled and incurable children in the Bethesda Home, Manchester, to be known as the "Arnold" cot; and £500 to endow a similar cot, to be known as the "Mary Seaton" cot.—Professor Lionel Smith Beale, F.R.S., has by will bequeathed £100 to King's College and £100 to King's College Hospital.—By the will of Mrs. Sarah Code, of Cornwall, £500 are bequeathed to the Penzance Infirmary and Dispensary, £200 to the Hospital for Sick Children, Great Ormond-street, London, and £200 to the Royal Hospital for Incurables, Putney.

CENTENARIANS.—The death occurred at Pontrhydyfen, Glamorganshire, on April 24th, of Mrs. Mary Thomas who was 105 years of age, having been born at Carmarthen on March 25th, 1801.—Mr. J. Carne, the parish clerk of St. Columb Minor, Cornwall, celebrated the 100th anniversary of his birthday on May 3rd. He was entertained at a public tea in the schoolroom in the evening and was afterwards presented with an oak armchair on which was an inscription recording the fact that it was given to him on his hundredth birthday.

ROYAL DEVON AND EXETER HOSPITAL.—On May 4th Mrs. Nosworthy of Dawlish formally opened the new operating theatre at the Royal Devon and Exeter Hospital. There was a large attendance, including the Countess of Iddesleigh and Sir Charles and Lady Follett. The operating theatre, which is a gift from Mrs. Nosworthy to the hospital, had been fitted up according to modern requirements and was erected at a cost of £1800. Dr. J. Delpratt Harris, the senior honorary surgeon to the hospital, in a short speech thanked Mrs. Nosworthy for her generosity and on behalf of the surgical staff presented her with a framed tracing of the foundation-stone of the institution, the position of which was only quite recently discovered. It bore the inscription: "Devon and Exeter Hospital; founded A.D. 1741."

SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.—The annual general meeting of the above society was held on May 3rd at 11, Chandos-street, Cavendish-square, W., Mr. Willett, Vice-President, being in the chair.—The proceedings were opened by the Chairman referring to the great loss which the society had sustained by the death of the late President, Mr. Christopher Heath, who had always taken the greatest interest in the society's welfare and had been a most regular attendant at its meetings. A formal motion of condolence was passed. A vote of thanks was moved to the editors of the medical journals for their courtesy in inserting the reports of the society from time to time; this was carried unanimously. During the year six new members were elected, five members died, and two resigned. At the end of the year there were 148 life members and 149 subscribers. Four widows were elected and two widows died, there being 54 in receipt of pensions at the end of the year. Three orphans were elected, making a total of 19 in receipt of pensions. The income derived from the invested funds of the society was £3098 19*s.* 2*d.*, from subscriptions £300 6*s.* 2*d.*, from donations £23 1*s.*, from life subscriptions £134 8*s.*, and a legacy of £250 had been received during the year. £3241 had been distributed among the annuitants of the charity. The working expenses of the society for the year were £248 16*s.* 7*d.* Dr. George Fielding Blandford was unanimously elected President and Dr. F. de Havilland Hall one of the treasurers. Six directors were elected in place of the six senior who retired according to the by-laws.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Vaccination Prosecutions.

MR. PICKERSGILL has introduced a Bill in the House of Commons to provide that no prosecution under the Vaccination Acts shall be commenced without the authority of the guardians.

Grievances of Poor-Law Medical Officers.

The grievances of Poor law medical officers in Scotland were brought before the Secretary for Scotland by an influential deputation on May 8th. Mr. W. L. Muir of Glasgow read a statement on behalf of the Scottish Poor-law Medical Officers' Association which may be summarised as follows: "On the passing of the Local Government (Scotland) Act, 1894, the membership of parish councils was thrown open to all ratepayers, with the result that, in the small outlying parishes, chiefly in the Highlands and islands, many members of parish councils have been elected who are not socially or intellectually fit to be intrusted with the absolute control of their medical officers. The result has been a very serious increase in cases of injustice towards

Evelina Hospital for Sick Children, Southwark.—House Physician and House Surgeon. Salary £80 respectively, with board, residence, and washing. Also Assistant House Surgeon. Salary £70, with board, residence, and washing.

Fareham, Hants County Asylum.—Second Assistant Medical Officer, unmarried. Salary £175 per annum, with apartments, board, washing, and attendance.

Gateforth, near Selby, Leeds Tuberculosis Association Sanatorium.—Resident Medical Officer for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

Glasgow Samaritan Hospital for Women.—House Surgeon.

Great Northern Central Hospital, Holloway, N.—Surgeon to the Throat and Ear Department.

Hartshill, Stoke-on-Trent, North Staffordshire Infirmary and Eye Hospital.—Junior House Surgeon. Salary £50 per annum, with board, apartments, and washing.

Hospital for Women, Soho-square, W.—Surgeon Dentist.

London Hospital, Whitechapel, E.—Surgical Registrar.

Macclesfield General Infirmary.—*Junior House* Surgeon. Salary £50 per annum, with board and residence.

Maidstone, West Kent General Hospital.—Senior House Surgeon, unmarried. Salary £100 per annum, with board and residence.

New Hospital for Women.—House Physician, Resident Medical Officer, Senior Obstetric Assistant Anæsthetist, and Clinical Assistant.

North-Eastern Hospital for Children, Hackney-road, Bethnal Green, E.—House Surgeon for six months. Salary *at rate of* £60 per annum, with board, residence, and laundry.

North West London Hospital, Kentish Town-road.—Resident Medical *Officer and Assistant Resident Medical* Officer for six months. Salary at rate of £50 per annum, with board, residence, and washing.

Portsmouth Borough Asylum.—Assistant Medical Officer, unmarried. Salary £150, rising to £200, with board, lodging, and washing.

Royal Free Hospital, Gray's Inn-road, W.C.—Assistant to the Clinical Pathologist (salary £50 per annum), also Junior Obstetric Assistant and Assistant Anæsthetist. *All females.*

Royal Westminster Ophthalmic Hospital, West Strand, W.C.—Clinical Assistants. Also House Surgeon for six months. Honorarium £25.

St. Mary's Hospital, Paddington, W.—Surgeon.

Sheffield Children's *Hospital (East-end Branch)*.—House Surgeon. Salary £70 per annum, with board, lodging, and washing.

Sheffield Royal Hospital.—Assistant House Physician, unmarried. Salary £50 per annum, with board and lodging.

Sheffield, Royal Infirmary.—Junior Assistant House Surgeon. Salary £65 per annum, with board, lodging, and washing. Also Junior House Physician. Salary £60 per annum, with board, lodging, and washing.

Swansea General and Eye Hospital.—House Surgeon. Salary £75 per annum, with board, apartments, washing, and attendance.

Taunton and Somerset Hospital, Taunton.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

Tottenham Hospital, London, N.—House Surgeon. Salary £90 per annum, with residence, board, and laundry.

Victoria Hospital for Children, Tite-street, Chelsea, S.W.—*Surgeon to In*-patients. Also House Surgeon.

Western General Dispensary, Marylebone-road, N.W.—Honorary Surgeon.

Wigan, Royal Albert Edward Infirmary and Dispensary.—Junior House Surgeon. Salary £50 *per annum, with* board, washing, and apartments.

Winwick, Warrington, Lancashire County Asylum.—Locum Tenens Medical Officer *for* four to five *months*. Salary 4 guineas per week, with apartments, board, attendance, and washing.

The Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Cavendish, in the county of Suffolk.

Births, Marriages, and Deaths.

BIRTHS.

Jackson.—On May 7th, at Woodhouse, Bakewell, the wife of R. Houlton Jackson, M.R.C.S., L.R.C.P., of a daughter.

Porter.—On May 9th, at The Limes, Berkhamsted, the wife of Charles B. Porter, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

Williams.—On May 5th, at Queen Anne-street, Cavendish-square, the wife of Campbell Williams, *F.R.C.S.*, *of* a son.

Wilson.—On April 29th, at Tregea House, Penzance, the wife of W. R. Wilson, L.R.C.P. Irel., L.R.C.S. Irel., L.S.A. Lond., of a daughter.

MARRIAGES.

Cotter—Musson.—On April 7th, at St. Peter's Church, Fulham, by the Rev. Canon Townend, George Edmond Wentworth Cotter, M.A., M.B., B.C. Camb., M.R.C.S., L.R.C.P. Lond., son of the late Duncan Donald Darroch Cotter, Officer 6th Foot, County Cork, Ireland, to Muriel Isobel, youngest daughter of Samuel *James* Musson, of Upper Norwood.

Thurnell—Armstrong.—*On April 30th*, at St. Mark's Church, Rosherville, Herbert Leslie Thurnell, M.A. Cantab., M.D., to Margaret Mary, eldest daughter of the late John *Christopher* Armstrong, Surgeon, Eng., *and of* Mrs. Armstrong, of Springfield, Gravesend.

DEATH.

Baines.—On May 5th, at 11, Cranley-place, S.W., Matthew Baines, Esq., V.D., M.D. Lond., Knt. of Grace of the Order of St. John of Jerusalem.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, *Marriages, and Deaths.*

Notes, Short Comments, and Answers to Correspondents.

AMERICAN ADVERTISEMENTS.

Mark Twain once wrote a small article entitled "Hogwash" in which he girded at certain forms of American journalism. Latterly American ways have affected British journalism, more especially in the advertisement department, and "hogwash" results. A flagrant instance of this now lies before us in the shape of a two-column advertisement which appeared in the *Daily News* of April 24th. It is headed "*Famous Medical Consultations*" and is "specially written by Howard Langdale." After referring to the illness of the "late Vice Reine" of India, the illness of the King in the Coronation year is mentioned and also that of the late Emperor *Frederick. Then comes the impassioned personal* note with which the quack of to-day lures his victim on. "You to-day who are suffering, you whom illness has claimed for your own, this is not your natural state. The remedy you need, the power that will bring the blossoms of hope blooming to your eyes, is at hand." The remedy, we find lower down, is Page Woodcock's pills. "Every box contains concentrated health and joyous relief." In another part is the *following: "Page Woodcock's pills* positively cure indigestion and all liver troubles, no matter of how long standing; also biliousness, spasms, *constipation*, severe headaches, *heartburn*, anæmia, and female ailments, as over 50 years' experience has proved. ... ..." Now this statement is a deliberate untruth and Page Woodcock, Limited, must know this perfectly well; and so should the advertisement manager of the *Daily News* if he exercises any control over his advertisements. Not that the *Daily News* is a bit worse in the matter of deceiving advertisements than certain other journals and, above all, than the popular sixpenny *monthly* magazines, but such an advertisement is infinitely more demoralising than the result of a race, which the *Daily News* will not print.

The article, we should add, is illustrated with pictures which are supposed to be portraits of Lady Curzon, Sir F. Laking, Sir F. Treves, Sir Thomas Barlow, Sir Morell Mackenzie, and Page Woodcock. That of Lady Curzon is no concern of ours but those of the three living *medical* men would afford excellent grounds for a libel action. However, we suppose that the stuff from which we have quoted appeals to a large class of mind and fills the pockets of the quacks who put it forth. The quack, as was his prototype in Eden, *is more* subtle than any beast, but we still await the time when he shall be called upon to pay a heavy licence for the right to deceive.

TWO PRESENT DAY EVILS IN PARODY.

Among the results of the *Westminster Gazette's* weekly prize *competitions* are the following *parodies which tersely* state the truth with regard to two evils, one the result of ignorance and the other the *result of* knowledge—that is to say, knowledge of the patience and long suffering of the public and the tortoise-like movement of the law where public welfare is concerned:—

They Were Seven.

"I met a little baby-boy
Who, in a 'pram' propelled,
Gnawed on a rich pork-pie with *joy*—
And having gnawed, he yelled.

His sister stopped and bought some gin,
But ere it could go down
I stayed her, crying 'What a sin!'—
And met a wondering frown.

'Sisters and brothers this way fed,
How many of them die?'
'We've buried seven in all,' she said,—
'I'm not surprised,' quoth I."

"I caught an 'Arrow' passing the Square,
It seemed to go—well, anywhere;
But, though swiftly it flew, the smell
Somehow followed it fairly well.'"

A BREACH OF TRUST.

To the Editors of The Lancet.

Sirs,—The vaccination inspector of the Local Government Board visited me a short time ago. In the course of showing him specimens of my work we visited a *woman lately* come to the village. After examining my vaccination he asked if an older child had been vaccinated. The mother replied that it had by Dr. X—— of Y——, and she added that she had asked that it should be vaccinated in only two places, but Dr. X—— had replied that he was bound to vaccinate in four places, but that *only two places would take*. The inspector remarked that Y—— was in his district and made careful notes. It was evident from the arm that only *two* places had taken.

I am, Sirs, yours faithfully,

May 6th, 1906.

O. C. J.

of births, deaths, and marriages from communicating particulars of the deaths occurring in their districts for publication in the local press; and whether, if such an order was now in force, there would be any objection to rescinding it.—Mr. BURNS answered: There was no new order on this subject in 1904, but in that year the Registrar General issued a circular with a view to the stricter observance of a regulation which had long been in force and which forbids a registrar of births and deaths to publish any statement of facts respecting the registration of births or deaths without the permission of the Registrar-General. I am not prepared to interfere with the discretion of the Registrar-General in the matter.

The Prime Minister and Infantile Mortality.

Mr. GODFREY BARING asked the First Lord of the Treasury whether his attention had been called to that passage in the report of the Registrar-General dealing with the high death-rate amongst infants; and whether he had considered the desirability of appointing a Royal Commission to inquire into infantile mortality and its causes.—Sir HENRY CAMPBELL-BANNERMAN said: My attention has been called to the part of the report referred to. The subject of infantile mortality and its causes is receiving the careful consideration of the Government but we do not see our way at present to the appointment of a Royal Commission to inquire into this most important subject.

Charge for Death Certificates.

Mr. SUMMERBELL asked the President of the Local Government Board whether he could give the number of death certificates issued to relatives of deceased members of friendly collecting societies during the period Jan. 1st to March 31st, 1906; the number of death certificates issued to relatives of deceased members of trade unions during the period Jan. 1st to March 31st, 1906; the number of death certificates issued to relatives of deceased assurants in the assurance companies during the period Jan. 1st to March 31st, 1906; and whether he would state why a uniform charge of 1*s.* or 1*s.* 3*d.* per certificate of death should not apply equally in respect to claims on assurance companies as to claims on friendly collecting societies.—Mr. BURNS answered: I am informed by the Registrar General that the certificates referred to are issued by local registrars only and that no returns of the numbers of such certificates are, or ever have been, received at the Central Office. He further states that if returns were required they would have to be specially collected from more than 2000 registrars in England and Wales alone and when obtained the certificates could not be classified according to the descriptions in the question. He adds that the value of such a return would not be commensurate with the trouble and expense of its preparation. As regards the last part of the question, I may point out that the charges referred to are fixed by statutory provisions which do not apply to assurance companies.

TUESDAY, MAY 8TH.

Enteric Fever at Darenth.

Mr. PIKE PEASE asked the President of the Local Government Board whether his attention had been called to the successive outbreaks of enteric fever during the past two years at the Metropolitan Imbecile Asylum at Darenth, Kent, traceable to broken drains and to the fact that the drains of this asylum were used to irrigate portions of the inclosure and that the contents finally disappeared into the chalk upon which the asylum stood; and whether, seeing that this inclosure was within five furlongs from the Darenth pumping-station of the Metropolitan Water Board, and at a higher level, he would state what steps he proposed to take.—Mr. BURNS replied: I am aware that there have been occurrences of enteric fever at the asylum during the past two years and that the first of them was supposed to be due to a defect in the drainage. It is the case that the drainage of the asylum is disposed of by irrigation on the asylum farm but I understand that the land is at a considerable distance from the Darenth well and that the local conditions are such that there would appear to be no risk of the well becoming polluted from anything that may happen at the asylum I will, however, communicate further with the Metropolitan Water Board on the subject.

BOOKS, ETC., RECEIVED.

AMERICAN CLIMATOLOGICAL ASSOCIATION (Secretary, Dr. GUY HINSDALE, Hot Springs, Virginia, U.S.A.).

Transactions of the American Climatological Association. For the year 1905. Vol. XXI. Price not stated.

CHURCHILL, J. AND A., 7, Great Marlborough-street, London, W.

On Carbohydrate Metabolism. (A Course of Advanced Lectures in Physiology delivered at the University of London, May, 1905). With an Appendix on the Assimilation of Carbohydrate into Proteid and Fat. Followed by the Fundamental Principles, and the Treatment, of Diabetes Dialectically Discussed. By F. W. Pavy, M.D., LL.D., F.R.S., Honorary Physician to King Edward VII. Hospital, Consulting Physician to Guy's Hospital. Price 6*s* net.

CLARENDON PRESS, Oxford.

Handbook of Anatomy for Art Students. By Arthur Thomson, M.A., M.B., Professor of Anatomy in the University of Oxford. Third edition. Price 16*s.* net.

CONSTABLE, ARCHIBALD, AND COMPANY, LIMITED, 16, James-street, Haymarket, London, S.W.

Physiology of the Nervous System. By J. P. Morat, of the University of Lyons. Authorised English Edition. Translated and edited by H. W. Syers, M A., M.D. Cantab., Physician to the Great Northern Central Hospital. Price 31*s.* 6*d.* net.

With Descriptions of Two New Dermanyssid Acarids by Robert Newstead, A.L.S., F.E.S., &c., and the Anatomy of the Proboscis of Biting Flies by J. W. W. Stephens, M.D. Cantab., and Robert Newstead, A.L.S., F.E.S., &c. March, 1906. Price 7*s.* 6*d.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ANDERSON, A. G., M.B., Ch.M. Sydney, has been appointed Clinical Assistant to the Chelsea Hospital for Women.

BULKELEY, L. A. H., M.B., B.S. Durh., has been appointed Junior House Physician at the Royal Infirmary, Newcastle-on-Tyne.

CARTER, F. BOLTON, M.D., M.S. Lond., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Leicester Infirmary.

CUNNINGHAM, H. B., M.B., B.S. Durh., has been appointed House Surgeon at the Royal Infirmary, Newcastle-on-Tyne.

DICK, W., L.R.C.S., L.R.C.P., has been appointed House Surgeon at the Children's Hospital, Bradford.

DUFF, DONALD, F.R.C.S. Edin., F.F.P.S. Glasg., has been appointed Extra Dispensary Surgeon to the Glasgow Royal Infirmary.

HEDDEN, RICHARD, L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed to the Medical Charge of Troops in the Honiton (Devon) Camp.

JONES, BERESFORD, M.B., B.S. Durh., has been appointed House Surgeon at the Royal Infirmary, Newcastle-on-Tyne

LEE, H. F., M.B., C.M. Edin., has been appointed Clinical Assistant to the Chelsea Hospital for Women.

LUNN, W. E. C., M.B., B S. Durh., has been appointed House Surgeon at the Royal Infirmary, Newcastle-on-Tyne.

SHAW, CHARLES J., M.B., M.R.C.P. Edin., has been appointed Senior Assistant Medical Officer at the Royal Asylum, Sunnyside, Montrose.

STACK, EDWARD HUGH EDWARDS, M.B., B.C. Cantab., F.R.C.S., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Orthopædic Hospital and Home for Crippled Children, Bristol.

TATE, E., M.B., B.S. Durh., has been appointed House Surgeon at the Royal Infirmary, Newcastle-on-Tyne.

WILLAN, R. J., M.B., B.S. Durh., has been appointed House Surgeon at the Royal Infirmary, Newcastle-on-Tyne.

WORGER, RICHARD GEORGE, L.R.C.P. Lond., M.R.C.S., L.S.A., has been appointed Medical Officer and Public Vaccinator for the Radstock District (Somerset).

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

ARMY MEDICAL SERVICE.—Examination of Candidates for not less than Forty Commissions.

BIRKENHEAD BOROUGH HOSPITAL.—Junior Resident House Surgeon. Salary £80, with fees.

BIRKENHEAD UNION INFIRMARY, WORKHOUSE, AND SANATORIUM.—Resident Assistant Medical Officer. Salary £120 per annum, with board, washing, and apartments.

BIRMINGHAM AND MIDLAND HOSPITAL FOR SKIN AND URINARY DISEASES, John Bright-street, Birmingham.—Clinical Assistant. Honorarium at rate of 52 guineas per annum.

BRECKNOCK COUNTY AND BOROUGH INFIRMARY.—Resident House Surgeon, unmarried. Salary £100 per annum, with apartments, board, attendance, fire, and gas.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Honorary Assistant Physicians.

BUXTON, DERBYSHIRE, DEVONSHIRE HOSPITAL.—Assistant House Surgeon. Salary £70 per annum, with apartments, board, and laundry.

COLCHESTER, ESSEX AND COLCHESTER GENERAL HOSPITAL.—House Physician. Salary £60 per annum, with board, washing, and residence.

DUDLEY, GUEST HOSPITAL.—Assistant House Surgeon for six months. Salary £40 per annum, with residence, board, and washing.

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Shadwell, E.—Dental Surgeon.

EPIDEMIOLOGICAL SOCIETY (11, Chandos-street, Cavendish-square, W.)—8.30 P.M. Paper:—Prof. R. Boyce (Liverpool): The Yellow Fever Epidemic in New Orleans in 1905.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (14th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M.: Dr. G. Little: Clinique. (Skin) 5.15 P.M. Lecture:—Mr. C. R. B. Keetley: (1) Appendicostomy; (2) Tuberculosis of the Cæcum.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M. Dr. Low: Tropical Medicine. 12 noon: Pathological Demonstration. Mr. Baldwin: Practical Surgery. 2 P.M. Medical and Surgical Clinics. 4 P.M. Mr. Dunn: Ophthalmology. 5 P.M. Dr. Saunders: Examination of Gastric Contents.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M. Operations. Sir D. Duckworth: Medicine. 3.15 P.M. Mr. W. Turner: Surgery. 4 P.M. Dr. StClair Thomson: Throat and Ear. Out-patient Demonstrations:—10 A.M. Surgical and Medical. 12 noon. Ear and Throat.

CHARING CROSS HOSPITAL.—4 P.M. Dr. Mercer: Demonstration (Mental). (Post-Graduate Course.)

TUESDAY (15th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. B. Abrahams: Clinique. (Medical.) 5.15 P.M. Lecture:—Mr. H. J. Paterson: Gastric Ulcer.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M. Medical and Surgical Clinics. 3 P.M. Dr. S. Taylor: Demonstration in Medical Wards. 5 P.M. Mr. Armour: Intestinal Obstruction.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M. Operations. Dr. R. T. Hewlett: Medicine. 3.15 P.M. Mr. Carless: Surgery. 4 P.M. Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M. Surgical and Medical. 12 noon. Skin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Clinical Lecture:—Dr. R. Russell: Cerebral Tumours.

NORTH EAST LONDON POST GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 P.M. Lecture:—Dr. G. N. Meachen: Diagnosis and Treatment of Ringworm.

ROYAL INSTITUTE OF PUBLIC HEALTH (37, Russell-square, W.C.).—5 P.M. Mr. W. R. Smith: The Law of Public Health. (Lectures III. and IV.)

WEDNESDAY (16th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. A. H. Tubby: Clinique. (Surgical). 5.15 P.M. Lecture:—Dr. G. H. Savage: Dementia Præcox.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—11 A.M. Dr. Davis: Examination of Throat, Nose, and Ear. 12 noon. Dr. Russell: Medicine. 2 P.M. Medical and Surgical Clinics. 5 P.M. Dr. Beddard: Practical Medicine. (Lecture I.)

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M. Operations. Dr. F. Taylor: Medicine. 3.15 P.M. Mr. M. Robson: Surgery. 4 P.M. Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M. Surgical and Medical. 11 A.M. Eye.

UNIVERSITY COLLEGE HOSPITAL (Gower-street, W.C.).—4 P.M. Clinical Lecture:—Dr. B. Shaw: Types of Pulmonary Tuberculosis from the Point of View of Treatment (with illustrative cases).

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Demonstration:—Dr. W. Wingrave: Pathology.

ROYAL INSTITUTE OF PUBLIC HEALTH (37, Russell-square, W.C.).—5 P.M. Dr. C. Prausnitz (Breslau): The Bacteriology of Water, Milk, and Tuberculosis. (Lecture II.)

THURSDAY (17th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Mr. Hutchinson: Clinique. (Surgical). 5.15 P.M. Lecture:—Dr. H. Campbell: Observations on Treatment.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M. Medical and Surgical Clinics. 4 P.M. Mr. S. Edwards: Demonstration in Surgical Wards. 5 P.M. Mr. Baldwin: Practical Surgery.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M. Operations. Dr. G. Rankin: Medicine. 3.15 P.M. Sir W. Bennett: Surgery. 4 P.M. Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 A.M. Surgical and Medical. 12 noon. Ear and Throat.

NORTH-EAST LONDON POST GRADUATE COLLEGE (Tottenham Hospital, N.).—4.30 P.M. Demonstration:—Mr. H. Cooper: Electrical Treatment.

CHARING CROSS HOSPITAL.—4 P.M. Mr. Hunter: Demonstration (Surgical).

HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.).—4 P.M. Lecture:—Dr. Poynton: Congenital Heart Disease.

FRIDAY (18th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. D. Grant: Clinique. (Ear).

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M. Medical and Surgical Clinics. 5 P.M. Mr. Armour: Diagnosis of Appendicitis.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich).—2.30 P.M. Operations. Dr. R. Bradford: Medicine. 3.15 P.M. Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M. Surgical and Medical. 12 noon. Skin.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Clinical Lecture:—Sir V. Horsley: Cerebral Surgery.

SATURDAY (19th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—2 P.M. Medical and Surgical Clinics. Dr. Baldani: Demonstration in Medical Wards.

LONDON SCHOOL OF CLINICAL MEDICINE (Dreadnought Hospital, Greenwich.)—2.30 P.M. Operations. Out-patient Demonstrations:—10 A.M. Surgical and Medical. 11 A.M. Eye.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.			
One Year	£1	12	6
Six Months	0	16	3
Three Months	0	8	2

TO THE COLONIES AND ABROAD.			
One Year	£1	14	8
Six Months	0	17	4
Three Months	0	8	8

Subscriptions (which may commence at any time) are payable *in advance*. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

"A WARNING."

To the Editors of THE LANCET.

SIRS,—The letter of complaint by the "Victim" in THE LANCET of April 28th is very misleading to the British medical public as regards the inclusion of the Indians within the same brackets as the Eurasians. In the first place, it is a mortal offence to the Eurasian to be classed in any way with the Indian. The term "Eurasian" (though there are many exceptions) is generally understood to be in India the progeny of the Europeans with the lowest classes of India. So, fortunately or not, the Indians of the better classes have nothing in common with the Eurasians as a class. There are plenty of Indians as medical practitioners and assistants in Britain and they have been a great success here. It will be a great pity if their interests should suffer for the reckless conduct of a "Eurasian." Again, we must confess we do not understand what the "Victim" means when he says: "To revenge himself upon any ...... in a manner quite Eastern in its completeness." In his great distress the poor "Victim" forgets that it was the Eastern prophets who first taught the world to do good for evil but not take delight in revenge. We trust very sincerely that the facts of the "Victim" will be proved and this "half-white" Othello's occupation will be gone. There are good men and bad men all the world over, even in Britain as well as in India, and the medical profession, calling itself the noblest profession in the world, must learn to discriminate—in the twentieth century at least.

We remain, Sirs, yours faithfully,
D. S. RAMACHANDRA RAO, M.A., M.B., Ch.B. Edin.
R. N. COORLAWALA, L.R.C.P. Edin., D.P.H. Cantab.
Coram-street, W.C., May 9th, 1906.

OXYGENATION OF REBREATHED AIR.

THE *Times Engineering Supplement* of May 9th states that the Niagara Electro-Chemical Company is manufacturing a form of peroxide of sodium which has the *property of emitting free oxygen* when brought into contact with moist carbon dioxide. An experiment has been made by shutting a man up in an air-tight box, two pounds of this peroxide being inclosed in the box with him. The size of the box was such that the air in it would have sufficed him for not more than 20 minutes but the sodium peroxide enabled him to remain in the box without any sort of detriment for six hours.

AN UNFORTUNATE CIRCULAR.

To the Editors of THE LANCET.

SIRS,—Mr. J. Munro Roger seems to have entirely missed the point his letter of April 30th. I never supposed that Dr. Moyle O'Connor had any previous knowledge of the intention to issue the obnoxious circular, but permit me to point out that it is one thing to announce in the descriptive pamphlet of the advantages of a block of flats that there is a doctor residing upon the premises but quite another to issue a *circular to every tenant pointing out that a particular medical man has* been officially "appointed physician" to the estate, and although that course may have been adopted in other cases "two wrongs do not make a right."

Yours very sincerely,
May 6th, 1906. YOUR PREVIOUS CORRESPONDENT.

MOTOR CARS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—Would any of your readers who have possessed, and thoroughly tested the cost of the running of, a car as described, minus the wages of driver, kindly supply me with the desired information. What would be the cost of the upkeep of a car for a year, going, say, on the average 20 miles a day on good hilly country roads, the car being a 12 to 16 horse power, four-cylinder, French make, weight about 18 cwt., and seated for four people, tyres 810 × 90 m.

I am, Sirs, yours faithfully,
May 5th, 1906. $Fe_2O_3(H_2O)_3$.

◆

Phosphates.—1. Apocodeine hydrochloride is used in France to some extent as a laxative. The passage as printed is correct. 2. Iodo-acetone is a solution of iodine in acetone of the strength of 1 in 5 or 1 in 10.

ERRATUM.—In Dr. Gordon Sharp's letter, headed "100 Consecutive Cases of Measles without Chronic Middle-ear Disease," which was published on p. 1280 of THE LANCET of May 5th, the words "half a fluid drachm of solution of ammonia" should read "*half a fluid* drachm of solution of *acetate* of ammonia."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Bolton Journal and Guardian, Westminster Gazette, Rotherham Advertiser, The Down Recorder, Sheffield Telegraph; Stafford Sentinel, Sheffield Independent, Lancashire Post, East London Advertiser, Evening Standard, Cork Examiner, Birmingham Gazette, Dublin Express, Hammersmith Observer, Manchester Courier, Dublin Evening Mail, Bexhill Chronicle, Newcastle Evening Chronicle, Scotsman, Manchester Guardian, Aberdeen Journal, Hereford Times, Dundee Advertiser, Belfast News Letter, Aberdeen Weekly Free Press, Bradford Observer Budget, Belfast Whig, Isle of Man Weekly Times, &c.*

WEDNESDAY (16th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., *Dental*, 2 P.M.).

THURSDAY (17th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), *University College* (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.).

FRIDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern *Central* (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), *Children*, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), St. Mark's (2.30 P.M.).

SATURDAY (19th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), *Charing Cross* (2 P.M.), *St. George's* (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (14th).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8 P.M. General Meeting. 8.30 P.M. Papers:—Mr. W. H. Battle: Method of Operation for the Radical Cure of Femoral Hernia.—Mr. H. J. Curtis: A Successful Case of Appendicitic Abscess and Multiple Liver Abscess, Appendicectomy and *Drainage*.

TUESDAY (15th).—PATHOLOGICAL SOCIETY OF LONDON (20, Hanover-square, W.).—Card Specimens will be shown by *Dr. Lawrence* and Dr. C. Lockyer. Dr. V. Bonney, Dr. J. Bernstein, Dr. J. Teacher (Glasgow), Mr. Hicks, Dr. Williamson, and Dr. Spilsbury: Chorion-epithelioma.—*Dr. J. Fawcett*: Diphtheria of Œsophagus and Bronchi.

WEDNESDAY (16th).—ROYAL MICROSCOPICAL SOCIETY (20, Hanover-square, W.).—8 P.M. Exhibition of Pond Life.

FRIDAY (18th).—SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN (11, Chandos-street, Cavendish-square, W.).—5.30 P.M. Wightman Lecture. Dr. A. Broca (Paris): Appendicitis in Childhood.

Three Lectures
ON
THE PRESERVATION OF HEALTH AMONGST THE PERSONNEL OF THE JAPANESE NAVY AND ARMY.

Delivered at St. Thomas's Hospital, London, on May 7th 9th, and 11th, 1906,

BY BARON TAKAKI, F.R.C.S.ENG., D.C.L.,
LATE DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE IMPERIAL JAPANESE NAVY.

LECTURE I.

Delivered on May 7th.

MR. TREASURER AND GENTLEMEN,—I am here to-day owing to an invitation from the staff of St. Thomas's Hospital and Medical College. I feel that it is a great honour to me personally and also a great compliment paid to the medical profession of the Japanese empire, and I thank you all on their behalf for your cordial and friendly feeling towards us.

I think some of you are already aware that I was invited by Cartwright's Lecture Committee of the Alumni Association of the College of Physicians and Surgeons of Columbia University of New York to deliver the Cartwright lecture and I chose the Sanitation of the Japanese Navy and Army as the subject of my lecture. At that time I had no idea and never thought that I should be asked to speak before such a large and distinguished assembly as is present here to-day. But when I was in America I was requested by the staffs of this hospital and St. Thomas's Medical College to tell them some of my experiences and I could not resist accepting such an honour from this hospital, with which I may claim very close relation, in so much as I am one of the graduates of this ancient institution and have worked under this roof as house officer. The subject of my address here is the same as in the Cartwright lecture, the reason being that on this subject I may claim to having had some practical experience and knowledge on account of my long service in the navy.

TABLE I.—SHOWING THE GENERAL HEALTH OF THE NAVY.

Year.	Strength.	All diseases and injuries. Cases of disease or injury.	Ratio of cases per 1000 of strength.	Average ratio of cases per person per annum.	Died.	Ratio of deaths per 1000 of strength.	Invalided.	Ratio of invalided per 1000 of strength.	Cases of kak'ke or beri-beri. Cases of kak'ke.	Ratio of cases of kak'ke per 1000 of strength.	Died.	Ratio of deaths per 1000 of strength.	Invalided.	Ratio of invalided per 1000 of strength.
1878	4523	17,728	3928·45	3·93	56	12·37	44	9·72	1485	327·96	32	7·07	19	4·20

1882	4769	12,074	2531·77	2·53	103	21·60	30	6·29	1929	404·49	51	10·69	17	3·56
1883	5346	16,380	3063·97	2·90	85	15·90	28	5·24	1236	251·20	49	9·17	4	0·75
1884	5638	10,515	1865·02	1·81	45	7·98	44	7·80	718	127·35	8	1·42	1	0·18
1885	6918	6,666	992·48	0·91	49	7·08	33	4·77	41	5·93	—	—	1	0·14
1886	8475	4,874	577·46	0·52	63	7·43	52	6·14	3	0·35	—	—	—	—
1887	9016	3,954	434·22	0·40	55	6·04	56	6·15	—	—	—	—	—	—
1888	9184	3,679	400·59	0·40	65	7·08	48	9·15	—	—	—	—	—	—

Here I have Table I. showing various details from 1878–1888 and I am now going to explain all the details. From 1888 to the present day there have been no important changes. In looking over this table we find the average number of general diseases during 1878, 1879, and 1880 to be just over 4327 per 1000—that is, one sailor suffered 4·32 times every year. The death-rate averaged 16·34 per 1000 and the invaliding-rate 8·75. The number of beri-beri (kak'ke) patients was 349·33 per 1000. Those who died from it averaged 7·96 and those invalided 2·45. Therefore, the number of sailors lost through death and made invalids owing to general diseases was 24·09 per 1000 and those lost through death and invaliding from beri-beri 10·43 per 1000. If we now subtract 10·43 from 24·09 only 13·66 remain. Therefore it was clear that if beri-beri could be wholly exterminated the number of losses from illness would decrease to 13·66.

From 1881 to 1883 the number of cases of illness slightly decreased. In 1884 the general aspect of the health of the navy suddenly changed for the better and the number of general diseases as well as cases of beri-beri markedly decreased. The number of general diseases was 1865·02 per 1000—that is, one person became ill 1·8 times a year. Deaths per 1000 decreased to 7·98 and invalids to 7·80. The number of beri-beri cases averaged 127·35 per 1000. Deaths from it decreased to 1·42. Therefore, the average of deaths and invalids from general diseases decreased to 15·78 and that of beri-beri to 1·60 per 1000. Similarly in 1885 the number of general diseases decreased to 992·48 per 1000 and deaths to 7·08 per 1000. Beri-beri decreased to 5·93 per 1000 without death. So the number of deaths and invalids decreased to 12·14. In 1886 general diseases per 1000 averaged 577·46, deaths 7·43, and beri-beri 0·35, without death or invaliding. In 1887 general diseases per 1000 were 434·22, deaths 6·04, and invalids 6·15. In 1888 general diseases per 1000 averaged 400·59, deaths 7·08, and invalids 9·15. In short, the number of losses through deaths and invalids per 1000 in 1884 was 15·78, in 1885 12·14, in 1886 12·57, in 1887 12·19, and in 1888 16·33. If we now compare these five years with three years from 1878 to 1880 we find a marked decrease of general diseases and disappearance of beri-beri with corresponding decrease in the loss of sailors year by year. These good results must depend upon certain causes and in order to explain them I will first of all try to describe various important facts since the establishment of the Naval Medical Bureau in 1872.

THE ESTABLISHMENT OF THE NAVAL MEDICAL BUREAU.

The Naval Medical Bureau of the Japanese Empire was established for the first time in 1872. At that time there was no one who had a thorough idea of naval hygiene because up to that time there was no special sanitary work carried out by medical officers in our navy, and other officers thought that the necessity of medical men in the Navy was simply for treating diseases and wounded. Even the medical officers thought in the same way. They never had the slightest idea of doing anything in preventing disease or in general hygiene. Accordingly, the only medical record left from 1872 to 1877 was limited to the description of results of treatment, name of diseases, and names of patients taken into hospitals. Between 1878 and 1883 the record gradually began to include facts about hospital and non-hospital patients and some hygienic affairs. Finally, from 1884 the records became more and more complete, giving various tables illustrating hygienic conditions by the issue of instructions relating to the duties of the medical officers.

Communications, Letters, &c., have been received from—

Three Lectures
ON
THE PRESERVATION OF HEALTH AMONGST THE PERSONNEL OF THE JAPANESE NAVY AND ARMY.

Delivered at St. Thomas's Hospital, London, on May 7th 9th, and 11th, 1906,

BY BARON TAKAKI, F.R.C.S. ENG., D.C.L ,
LATE DIRECTOR-GENERAL OF THE MEDICAL DEPARTMENT OF THE IMPERIAL JAPANESE NAVY.

LECTURE I.

Delivered on May 7th.

MR. TREASURER AND GENTLEMEN,—I am here to-day owing to an invitation from the staff of St. Thomas's Hospital and Medical College. I feel that it is a great honour to me personally and also a great compliment paid to the medical profession of the Japanese empire, and I thank you all on their behalf for your cordial and friendly feeling towards us.

I think some of you are already aware that I was invited by Cartwright's Lecture Committee of the Alumni Association of the College of Physicians and Surgeons of Columbia University of New York to deliver the Cartwright lecture and I chose the Sanitation of the Japanese Navy and Army as the subject of my lecture. At that time I had no idea and never thought that I should be asked to speak before such a large and distinguished assembly as is present here to-day. But when I was in America I was requested by the staffs of this hospital and St. Thomas's Medical College to tell them some of my experiences and I could not resist accepting such an honour from this hospital, with which I may claim very close relation, in so much as I am one of the graduates of this ancient institution and have worked under this roof as house officer. The subject of my address here is the same as in the Cartwright lecture, the reason being that on this subject I may claim to having had some practical experience and knowledge on account of my long service in the navy.

Here I have Table I. showing various details from 1878–1888 and I am now going to explain all the details. From 1888 to the present day there have been no important changes. In looking over this table we find the average number of general diseases during 1878, 1879, and 1880 to be just over 4327 per 1000—that is, one sailor suffered 4·32 times every year. The death-rate averaged 16·34 per 1000 and the invaliding-rate 8·75. The number of beri-beri (kak'ke) patients was 349·33 per 1000. Those who died from it averaged 7·0[illegible] invalided 2·45. Therefore, the number of sailors lost through death and made invalids owing to general diseases was 24·09 per 1000 and those lost through death and invaliding from beri-beri 10·43 per 1000. If we now subtract 10·43 from 24·09 only 13·66 remain. Therefore it was clear that if beri-beri could be wholly exterminated the number of losses from illness would decrease to 13·66.

From 1881 to 1883 the number of cases of illness slightly decreased. In 1884 the general aspect of the health of the navy suddenly changed for the better and the number of general diseases as well as cases of beri-beri markedly decreased. The number of general diseases was 1865 02 per 1000—that is, one person became ill 1·8 times a year. Deaths per 1000 decreased to 7·98 and invalids to 7·60. The number of beri-beri cases averaged 127·35 per 1000. Deaths from it decreased to 1·42. Therefore, the average of deaths and invalids from general diseases decreased to 15·78 and that of beri-beri to 1·60 per 1000. Similarly in 1885 the number of general diseases decreased to 992·48 per 1000 and deaths to 7·08 per 1000. Beri-beri decreased to 5·93 per 1000 without death. So the number of deaths and invalids decreased to 12·14. In 1886 general diseases per 1000 averaged 577·46, deaths 7·43, and beri-beri 0·35, without death or invaliding. In 1887 general diseases per 1000 were 434·22, deaths 6·04, and invalids 6·15. In 1888 general diseases per 1000 averaged 400·59, deaths 7·08, and invalids 9·15. In short, the number of losses through deaths and invalids per 1000 in 1884 was 15·78, in 1885 12·14, in 1886 12·57, in 1887 12·19, and in 1888 16·33. If we now compare these five years with three years from 1878 to 1880 we find a marked decrease of general diseases and disappearance of beri-beri with corresponding decrease in the loss of sailors year by year. These good results must depend upon certain causes and in order to explain them I will first of all try to describe various important facts since the establishment of the Naval Medical Bureau in 1872.

THE ESTABLISHMENT OF THE NAVAL MEDICAL BUREAU.

The Naval Medical Bureau of the Japanese Empire was established for the first time in 1872. At that time there was no one who had a thorough idea of naval hygiene because up to that time there was no special sanitary work carried out by medical officers in our navy, and other officers thought that the necessity of medical men in the Navy was simply for treating diseases and wounded. Even the medical officers thought in the same way. They never had the slightest idea of doing anything in preventing disease or in general hygiene. Accordingly, the only medical record left from 1872 to 1877 was limited to the description of results of treatment, name of diseases, and names of patients taken into hospitals. Between 1878 and 1883 the record gradually began to include facts about hospital and non-hospital patients and some hygienic affairs. Finally, from 1884 the records became more and more complete, giving various tables illustrating hygienic conditions by the issue of instructions relating to the duties of the medical officers.

TABLE I.—SHOWING THE GENERAL HEALTH OF THE NAVY.

Year.	Strength.	All diseases and injuries. Cases of disease or injury.	Ratio of cases per 1000 of strength.	Average ratio of cases per person per annum.	Died.	Ratio of deaths per 1000 of strength.	Invalided.	Ratio of invalided per 1000 of strength	Cases of kak'ke or beri beri. Cases of kak ke.	Ratio of cases of kak ke per 1000 of strength.	Died.	Ratio of deaths per 1000 of strength	Invalided.	Ratio of invalided per 1000 of strength.

THE EDUCATION OF NAVAL MEDICAL OFFICERS.

At the time of the establishment of the Medical Bureau in 1872 Dr. Wheeler, attached to the British Legation, was invited by the Naval Hospital to give lectures, both theoretical and practical. In 1872 Mr. William Anderson was specially invited from England to teach junior medical officers and students. In 1877 16 men were qualified and passed out of the school. These were the first graduates. Chief among them were the present Surgeon-Generals Yamamoto, Totsuka, Suzuki, and Kimura. The first three were educated, like myself, in this hospital for the higher course of study. (Surgeon-General Yamamoto served during the late war with Russia as the chief surgeon of Yokosuka Naval Station, Surgeon-General Totsuka as the chief surgeon of Sasebo Naval Station, where the majority of the wounded from the naval fights were treated, and Surgeon-General Suzuki as the chief medical officer of Togo's fleets.) However, later, during my absence in England, the levying of medical students was stopped and Mr. Anderson's duties came to an end It was then found that as the newly adopted medical officers could not understand a foreign language they could neither learn anything about naval and military hygiene in foreign lands nor could they follow the progress of medical science in general. Besides, they could not talk and associate with foreign medical officers, and on occasions when they went to foreign ports or lands they could not find out the sanitary conditions, especially those relative to the endemic and epidemic diseases of those ports.

Again this ignorance of foreign languages led to inconveniences in buying articles of food, drinking water, &c., and thus there was always fear of the invasion of infectious diseases through this channel. Moreover, the foreign language used by the Imperial University in teaching medicine was German, and I thought that the language most useful and important to our naval medical officers would be English. Finally, unless those who serve in the navy were able to keep up the general spirit characteristic of the sailors they could not work hand in hand with the fighting or deck officers and they would find many inconveniences in conducting sanitary affairs. Accordingly I insisted upon re-establishing the Naval Medical School and enlisted some students in 1881. Besides the full medical course the English language was taught as an extra subject and by 1894 80 students in all passed out as officers. But after that year (in 1893 I retired from active service, was placed in the reserve list, and became a member of the House of Peers) fresh students were not again enlisted and new medical officers were obtained from among those who studied in the Imperial University and specially licensed medical schools. Medical officers were also sent abroad to pursue further study in medical science. In 1872 Dr. S. Ono and Dr. K. Yoshida, in 1874 Dr. T. Ishigami, in 1875 Dr. K. Takaki, and in 1878 Dr. A. Saneyoshi were sent to England. Since then a number of medical officers was sent to Europe, chiefly to England and Germany. I entered the navy in 1872 and began to treat the sick and wounded. What at once attracted my notice was the large number of beri-beri patients and the numerous deaths resulting from it. And as this disease truly played havoc with the health of our navy and killed many, so as greatly to reduce our fighting strength, I turned my full effort towards finding its cause and treatment. By doing so, I meant to prevent the outbreak of this disease and to provide against unforeseen danger through ill-health in time of crisis in our Empire. In pursuing this purpose I met with many difficulties and passed through years of hard work.

The first time I heard of the fearful nature of beri-beri was 44 years ago. At that time guards were despatched by several Daimios to Kyoto to act as protectors of the Imperial Palace and my father being one of them stayed there for over a year. On his return he told me of the disease called beri-beri which killed many of these men. They attributed the cause to food and called a provision box the "beri-beri box." Later, in 1868, that is, in the year of the Meiji Revolution, I served for eight months in the army of Prince Shimadzu but did not see any beri-beri. As I said before, I entered the navy in 1872 and began to treat beri beri patients for the first time. Up to May, 1875 I had seen several hundreds of beri-beri cases at the Naval Hospital. In the summer several acute cases appeared daily. Often five or six cases had to be treated at the same time and attending officers had to work very hard both day and night. At that time the beri-beri patients constituted three fourths of the whole number of patients. Various forms of treatment were adopted: purgatives and digitalis for œdema, palpitation, &c.; strychnine, iron, &c., for numbness and paralysis; tincture of aconite for hyper-sensibility of muscles; and purgatives and venesection for acute cases. These forms of treatment were general and there was no definite opinion as regards the food.

Conditions being such, it became my fixed desire to discover the cause and treatment of beri-beri. But I thought that with my insufficient knowledge of medical science I could not possibly discover them, and from then on the desire to go abroad in order to fit me for attaining my object never left my thoughts even for a moment. At last, in June, 1875, the desire was fulfilled and I started for England. I reached London in July and entered St. Thomas's Hospital Medical School in October. After staying there for over five years I returned to Japan in November, 1880, and was made the director of the Tokyo Naval Hospital in December. Thus, I got an opportunity to treat beri-beri patients again. The general conditions on my return were exactly the same as before I went to England and with subsequent increase of sailors more beri-beri cases appeared. At times, when the disease was in full force, we found the hospital too small and often had to use neighbouring temples. Moreover, acute cases were many and medical officers had a very busy and hard time. Such conditions used to strike my heart cold whenever I came to think of the future of our Empire, because, if such a state of health went on without discovering the cause and treatment of beri-beri our navy would be of no use in time of need.

As a first step towards the cause and cure of this disease I began to note the localities and seasons and to examine sailors in ships, barracks, &c, and I obtained the following facts:—1. Beri-beri occurred mostly from the end of spring to summer, but it was not limited to the warm season, sometimes occurring during the severe cold of winter. 2. The occurrence of the disease varied in different ships, barracks, &c. 3. Even in the same ship it appeared in some stations, not in others, and was never certain. 4. It occurred from time to time without regard to the state of quarters or clothing. 5. I found out that although clothing, food, living, &c, were not quite the same in all stations, yet they were almost similar.

With these facts I could not easily discover the cause and I went on with further investigations with the following results:—1. As regards the class of patients in general, I found that sailors, soldiers, policemen, students, shop-boys, and so on, were those who suffered most. The upper class rarely became affected. 2 The people living in the same place suffered unequally—that is, some suffered and others did not. 3. Although it occurred mostly in large cities, like Tokyo, Osaka, and Kyoto, yet it sometimes appeared in smaller towns as well. Thus with such results and without discovering the cause of beri-beri the time quickly passed to the year 1882. In February of the year 1882 I was appointed the Vice-Director of the Naval Medical Bureau.

About that time it was found to be necessary to provide an extra medical officer besides the usual number on board the training ships going for long cruises on account of the abundance of beri-beri cases among the men during the voyage. In 1882 there was a critical state of affairs with Korea and three warships were sent to Ninsen (Chemulpo) and Saibutsu Bay. They stayed there only 40 days but owing to shortness of hands caused by the prevalence of beri beri among sailors the officers felt quite unfit for battle and it was a very anxious time for those in positions of responsibility because those three ships would have been of no fighting value in the critical moment. For example, in one of the ships 195 out of 330 were down with beri-beri. As a consequence I handed to the chief of the Naval Medical Bureau on June 24th, 1882, a memorandum describing the facts. Following this, in August, 1882, H.I M S. *Fuso*, in spite of anchoring off Shinagawa Bay, had to send half of its crew ashore in turns for the treatment of beri beri. Continuing still further. I examined the reports of the Tokyo and Yokohama naval hospitals for 1881 and found out that three-fourths of the patients had suffered from beri-beri.

In 1883 I received permission from the Minister of the Navy to examine the hygienic conditions of ships, barracks, schools, &c., belonging to the navy. I found that although working hours, clothing, dwelling-houses, &c., were similar everywhere, yet in food there was a great deal of difference. So I now asked the head of each sectional department to send me in the reports describing the details of food taken three times daily for a week. From this I discovered the following facts: 1. Nitrogenous substances contained in the food were not sufficient to make up for the amount of nitrogenous substances discharged from the body. 2. On the contrary, the food contained too much carbohydrates. If we now look into the table recognised by scientists showing the comparative amounts of nitrogen and carbon discharged daily by a fair-sized adult we shall see that carbon equals 310 grammes and nitrogen equals 20 grammes—i.e., nitrogen is to carbon as 1 is to 15·5. 3. The food taken by our sailor showed nitrogen 1 to carbon 17–32. 4. The greater the difference in these proportions the more beri-beri occurred, and the lesser the difference the less.

After obtaining these important facts I came to think that:—1. Beri-beri is caused by the disproportion of nitrogenous and non-nitrogenous elements (nitrogen and carbon) in food—that is, the amount of the nitrogenous was insufficient and that of the non-nitrogenous excessive. 2. The symptoms of beri-beri patients are really due to these causes and the good results obtained by purgatives are due to their powers in getting rid of the abundant carbohydrates. 3. The pathological changes occurring in nerves, muscles, &c., are the result of inability of the tissues to repair the waste owing to the insufficiency of nitrogenous substances in the food and the above changes are further aggravated by the presence of the large quantity of carbohydrates in the food.

In October, 1882, I submitted a proposal to the Minister of the Navy, the late Count Kawamura, the chief object of which was to change the old dietary system. When this proposal was put forward before a meeting there was a good deal of opposition. They said that the change was too radical and instanced the great disturbances caused by the change of diet in the Italian navy some years before. They also called attention to the new system of fixing the amount of food by quality and quantity instead of by monetary value as in the old. In spite of the difficulties caused by this opposition my opinion finally prevailed and the new system was adopted. But as we required a few months longer in order to examine and to fix the quality and quantity of food to be given, and as even some naval medical officers were holding the opposite view in heart, I took the opportunity of trying the new system on a certain number of beri-beri patients in the Tokyo Naval Hospital, comparing the result with that of the old system. The following is the table showing the increase in weight in the old and new diet on ten beri-beri patients, five on each diet during four weeks:—

Old Diet. *New Diet.*

1 momme = 58 grains Troy, or about 1 drachm

Initials of Patients

	F—— K——*	U—— K——.*
	Momme	Momme.
Before experiment	13,000 (101 lb.)	12,700 (98½ lb.)
1st week	13,020 (increase 20=2½ oz.)	12,800 (increase 100=¾ lb.)
2nd week	13,040 (,, 20=2½ oz.)	12,800
3rd week	13,380 (,, 340=2½ lb.)	13,160 (increase 360=3 lb.)
4th week	13,440 (,, 60=7 oz.)	13,260 (,, 100=¾ lb.)
	Total increase 440=3½ lb.	Total increase 560=4½ lb.

	B—— I——*	T—— K——.*
	Momme.	Momme.

3rd week	10,920 (increase 60)	13,360 (,, 80)
4th week	10,950 (,, 40)	13,640 (,, 280)
	Total decrease 140=1 lb.	Total increase 320=2½ lb.

	Y—— K——†	G—— M——.†
	Momme.	Momme.
Before experiment	14,960	14,360
1st week	15,280 (increase 320)	14,320 (decrease 40)
2nd week	15,200 (decrease 80)	14,220 (,, 100)
3rd week	15,300 (increase 100)	14,270 (increase 50)
4th week	15,300	14,310 (,, 40)
	Total increase 340=2 lb.	Total decrease 60=½ lb.

	T—— K——.†	T—— W——.†
	Momme.	Momme.
Before experiment	13,500	12,740
1st week	13,340 (decrease 160)	12,660 (decrease 80)
2nd week	13,230 (,, 110)	12,500 (,, 160)
3rd week	13,180 (,, 50)	12,500
4th week	13,150 (,, 30)	12,440 (,, 60)
	Total decrease 350=2¼ lb.	Total decrease 300=2⅙ lb.

New Diet.

Increased weight of 5 experimental patients ... 1160 momme = 9 lb.
Decreased ,, 5 ,, ,, ... 360 ,, = 3 lb.

The difference between the two is the increase of 800 momme = 6 lb.—that is, each person increased 160 momme = 1·2 lb.

Old Diet.

Increased weight of 5 experimental patients ... 1340 momme = 10·38 lb.
Decreased ,, 5 ,, ,, ... 490 ,, = 3·8 lb.

The difference is the increase of 850 momme = 6½ lb.—that is, each patient increased 170 momme = 1·3 lb.

In this table those marked (*) show chronic kakke; those marked (†) show subacute kakke.

The new system diet for the first two weeks is shown in Table II.; that for the second two weeks in Table III. Table IV. shows the old diet. Of the five patients who received the new diet all were discharged with complete cure. Of the five patients who remained on the old diet four were cured and discharged from the hospital and one changed into pulmonary disease.

TABLE IV.—*Showing the Old System of Diet for Hospital Patient.*

	Breakfast.	*Luncheon.*	*Dinner.*
First class	Chief dish. Vegetables, two kinds, eggs, or peas, or beans, or sea-weeds, or eer (fish). Pickle. Plums (2). Boiled rice (rice gruel sometimes substituted).	Dish. Boiled fish or fried fish: 25 momme (3⅛ oz.). Small dish (cooked white bean). Boiled rice.	Dish. Chicken or beef: 25 momme (3⅛ oz.). Vegetables. Small dish (cooked white bean). Boiled rice.
Second class	Bread (¼ pound). Half-boiled eggs (2). Sugar: 4 momme (½ oz.). Salt.	Bread (vermicelli, &c.).	Dish. Chicken or beef: 15 momme (1⅞ oz.). Vegetables. Small dish. Plums (2). Rice gruel (100 mommes (12½ oz.).
Third class	Soup. Vegetables (2 kinds). Small dish. Pickled plums (2). Boiled rice.	Dish. Vegetable (1 to 3 kinds). Small dish (potatoes, Indian corn). Boiled rice.	Dish. Beef or fish or fried eggs. Vegetables. Small dish. Boiled white bean. Boiled rice.

As the result of these experiments it was found necessary to spend 36 sen 1 rin (about 8¾*d.*) daily instead of 18 sen (about 4¼*d.*) under the old system—that is, more than double. In December of the same year an order was issued to make monthly statistics of the body-weight of each person in the navy in order to ascertain the necessary amount of food for officers and men. By this means we got the following comparative scale of body-weight for five years from 1884 to 1888.

In looking over Table V. you will find that the body weight is highest during the months of February, March, and April, and lowest in August and September. Therefore after 1889 the weights were taken only in March and September every year.

During ten years from 1884 to 1893 there was more or less difference yearly, but, taken as a whole, the weight had increased, that is, nearly eight pounds per person. From 1894 to 1903, for ten years, there was not much change in weight, and I think that shows the sufficiency of food supplied. During the former ten years the number of general diseases decreased in accordance with the yearly increase of weight. The last ten years showed not much change in weight and number of diseases. On Sept. 26th, 1883, I for the first time spoke on the cause of beri-beri before the meeting of the Japan Society of Hygiene and expressed my view as to the cause of the disease. On Oct. 5th, 1883, I was promoted to be Director of the Medical Bureau. Soon afterwards I asked the Minister of the Navy to have a special committee of investigation on the cause of the occurrence of the almost unprecedented number of cases of beri-beri on board the training ship *Riujo*, which left Shinagawa on Dec. 19th, 1882, and returned to Shinagawa on Oct. 15th, 1883, after a voyage of 271 days to New Zealand, South America, and Hawaii. My proposal was adopted and a special committee consisting of the following members was formed: Rear Admiral Maki (Chairman), Surgeon-General Takaki, Captain Isobe, Commander Kunitomo, Fleet-Surgeon Kagami, Fleet-Surgeon Toyozumi, Paymaster Ijichi, Paymaster Kurihara, Secretary Iwamura, Lieutenant Serada, and Clerks Matsumura, Sakamoto, and Mishina.

The first meeting of the committee was held on Nov. 12th, 1883. The chairman, Admiral Maki, explained the object of this committee and I was appointed the chief of the investigation board. After this the meeting was held five times a week till April 11th, 1884, and altogether the committee met 79 times. During that time 76 records were made, comprising 10,862 questions and 10,400 answers. As a result I, with the assistance of Staff Surgeon Toyozumi, compiled ten reports concerning (1) patients, (2) clothing, (3) bedding,

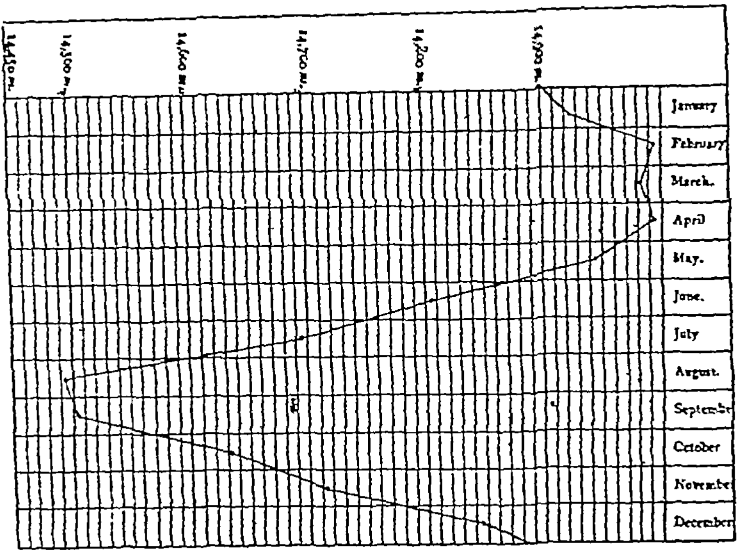

TABLE V.—*Average Monthly Body-weight of each Person from 1884 to 1888.*

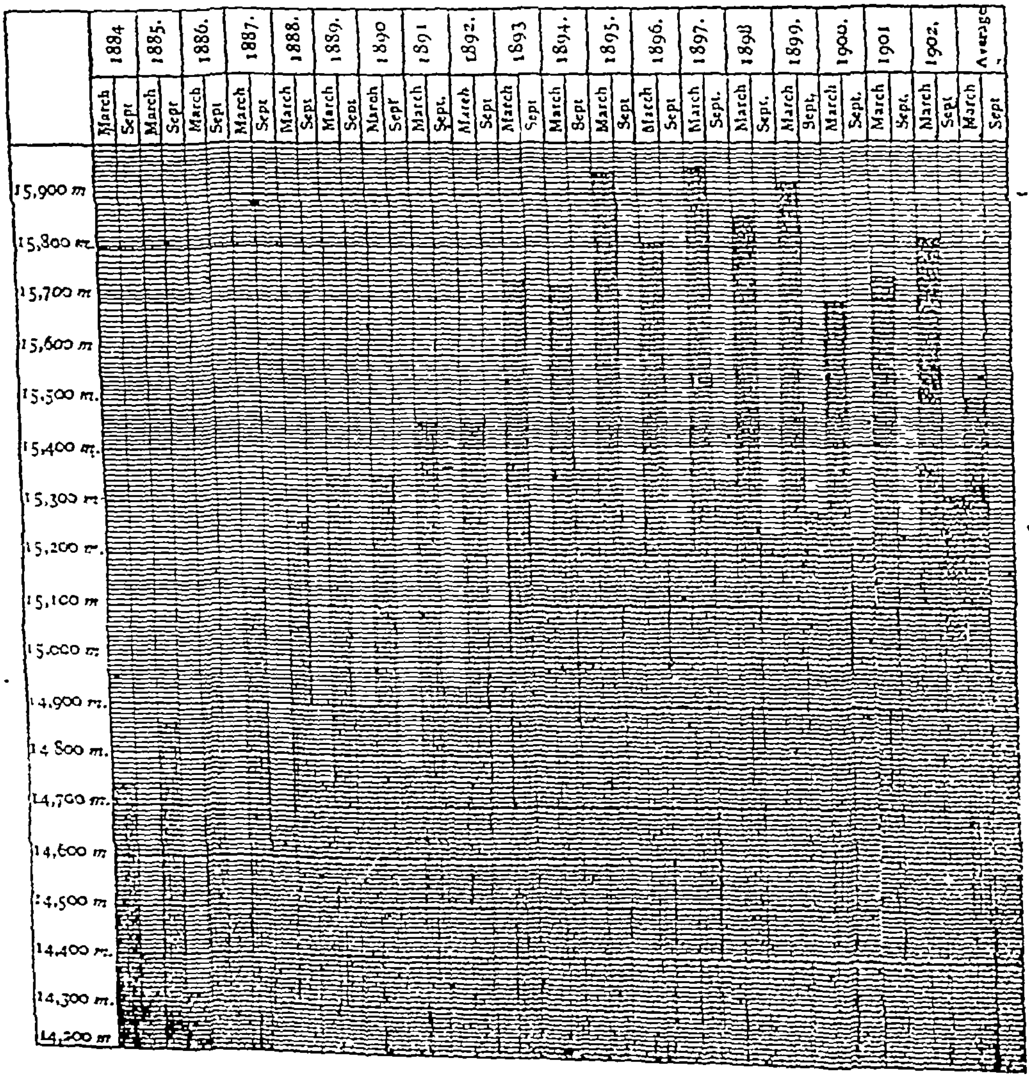
TABLE VI.—COMPARATIVE SCALE OF BODY-WEIGHT IN MARCH AND SEPTEMBER DURING 19 YEARS.



(4) food, (5) drink, (6) housing, (7) labour, (8) rest, (9) voyage, (10) anchorage, (11) weather and climate, and (12) conclusion. Besides, we made up six tables on diseases, 32 tables on food, one each on drink, climate, weather, and temperature, and also tables on food supplied daily to petty officers, sailors, students, gun-room officers, and officers. Finally, the committee met to discuss the results of investigations on Feb. 12th, 1885.

In November, 1883, I was informed of the sailing of the training-ship *Tsukuba* in a short time and at once arranged to utilise this opportunity of testing the new system of diet by making her go the same route as that of the *Riujo*. So before the sailing of the *Tsukuba* on Nov. 24th, 1883, I demanded the immediate practical application of the new diet and in consequence the Minister of the Navy issued the order to change the diet throughout the navy on Nov. 29th. Also on Nov. 26th, 1883, I proposed the necessity of the Medical Bureau having the reports on food supplied in ships, barracks, schools, &c., every month, and in the following December the Minister ordered this to be done. These reports have continued up to the present day.

TABLE VII.—*Showing the Average Daily Amount of Food for Each Person during 19 Years from 1884 to 1902.*

Year.	Amount of food for each person per day.	Year.	Amount of food for each person per day.
	Momme. Ounces.		Momme. Ounces.
1884	606 63 = 75·83	1894	416·08 = 52 01
1885	625·57 = 78·19	1895	406·70 = 50·83
1886	644·62 = 80·51	1896	384·90 = 48·11
1887	563·58 = 70·44	1897	391·29 = 48·91
1888	551·13 = 68 89	1898	406·75 = 50·84
1889	596·06 = 74·50	1899	408·01 = 51·00
1890	443 01 = 55·37	1900	415·45 = 51·93
1891	407·02 = 50·87	1901	460·60 = 57·57
1892	399 56 = 49·94	1902	438·55 = 54·82
1893	386·41 = 48·30		

The decrease of the amount of food since the year 1890 is due to the alteration of the Food Regulations in April of that year and also to the fact that, according to the revised regulations, when members of a table company exceed five in number they are allowed to receive per every five members (this number was altered to ten in 1898 and resulted in a little increase in the amount of food since that year) one man's allotment in money, with which they can buy whatever food they like, and such food is excluded from the Table. Some increase of the amount of food from 1900 is also due to the alteration of the Food Regulations from May of the same year.

1901	52·66 = 6·58	9 03 = 1·13	156 90 = 19·61	218 59	14
1902	38 61 = 4 82	8 59 = 1·07	162·16 = 20·26	209·36	16

The reason of decrease in the amount of nutritive elements since the year 1890 and that of some increase in it since the year 1898 is due to that stated in the note appended to Table VII. The present scale of diet supplied to the sailors is as follows:—

CHELSEA CLINICAL SOCIETY.—The ninth annual dinner of the Chelsea Clinical Society was held on May 3rd, under the chairmanship of the President of the society, Dr. J. B. Ball, at the Criterion Restaurant, Piccadilly, London. The feature of the evening was the brevity of the speeches and this unusual occurrence accounted for the great success of this dinner. The loyal toasts having been duly honoured the chairman proposed the "Chelsea Clinical Society," and after this had been acknowledged by Mr. A. F. Penny Dr. T. Vincent Dickinson promptly rose and submitted the toast of "The Visitors and Kindred Societies." This was responded to by Mr. C. R. B. Keetley and also by the Mayor of Chelsea. Dr. R. J. Collie in a few words then gave the toast of "The President and Officers of the Society," and the chairman in responding expressed in generous terms the thanks of the society for the services rendered by the honorary treasurer, Dr. A. E. Cooper, and the honorary secretary, Mr. A. A. Cooper. The evening was enlivened by some excellent music and dramatic recitals.

The Goulstonian Lectures

ON

AUTO-INTOXICATION: ITS RELATION TO CERTAIN DISTURBANCES OF BLOOD PRESSURE.

Delivered before the Royal College of Physicians of London on March 13th, 15th, and 20th, 1906,

BY H. BATTY SHAW, M.D. LOND.,
F.R.C.P. LOND.,

LECTURER IN THERAPEUTICS, UNIVERSITY COLLEGE, LONDON, ASSISTANT PHYSICIAN TO UNIVERSITY COLLEGE HOSPITAL AND TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.

LECTURE II.[1]

Delivered on March 15th

MR. PRESIDENT AND GENTLEMEN,—In my first lecture I drew attention to three points: (1) that in 12 out of 68 clinical cases hypertension was observed and that there was with one exception proof that the kidneys were affected in these cases; (2) that the explanation of hypertension in renal disease was unsatisfactory—a toxic cause had been invoked but not demonstrated; and (3) that experimentally I had shown that a rise of blood pressure occurred 18 times out of 19 in which kidney extract was used and that such frequency of a pressor effect was not noticed after the injection of extracts of organs other than the suprarenals—moreover, the pressor effect produced by kidney extract was a prolonged one. At this stage it was necessary to reconsider the statement made by Swale Vincent and Sheen that they had been able to *some extent* to corroborate the observations of Tigerstedt and Bergman,[2] inasmuch as they had found distinct evidence of the existence of a pressor substance in the kidney. The only figure given by Swale Vincent and Sheen in support of their findings shows a comparatively small rise and a small fall with a return to a level a little higher than the original height. In traces taken from my own series of animals it will be seen that there is often a *fall* and then the pressure rises and is maintained for some time. The different conditions of the animals must, however, be remembered. Swale Vincent and Sheen experimented on a dog, using A.C.E. mixture and presumably artificial respiration as well as morphine; whereas in my own experiments cats were used, anæsthetised by means of ether with spontaneous respiration, and the effect, as already mentioned, is certainly much more striking.

Turning to Tigerstedt and Bergman's paper, it is found that these two workers have ten years ago established results of a very different character from those given by Swale Vincent and Sheen, and I think that the results obtained in my small series of cats are in close agreement with the results obtained by Tigerstedt and Bergman, though in little else do I presume to compare my observations with those made by these workers. They had set themselves the task of elucidating the relationship between kidney and heart, being influenced by the teaching of Brown-Séquard on "internal secretion" and by the association existing between certain renal and cardiac diseases. Their first experiment was rewarded by an interesting result. Freshly excised rabbit's kidney was rubbed up with glass powder and physiological salt solution; the fluid obtained was then filtered and a few cubic centimetres were injected intravenously into rabbits. In a short time a well-marked and apparently protracted increase of arterial pressure was observed. In the first experiment within 80 seconds of the injection of five cubic centimetres of the extract the maximal pressure had risen from 70-65 millimetres before injection to 102 millimetres—i.e., an increase of pressure of about 50 per cent. had ensued; in a second experiment the increase after the injection of four cubic centimetres was 25 per cent. within 100 seconds; in the third experiment there was an increase of 18 per cent. in 60 seconds. The investigation was further elaborated. They found that extracts which were prepared by boiling the fresh kidney with water or extracts prepared from the boiled kidney by means of cold water were inactive; moreover, by boiling or heating the fresh extract the pressor effect was destroyed. An important discovery was that alcohol, either absolute or of 50 per cent. strength, was quite unable to extract from the preparation any active material. They were also able occasionally, but not always, to demonstrate that diluted glycerine extract had a definite pressor effect; the failures to produce a rise of pressure were attributed to the well-known depressor effect of the glycerine and in one experiment it was thought that the first injection of glycerine extract had produced a fall only. A second dose was given before the true effect of the first one had shown itself and after 140 seconds the pressor effect of the second dose was found to have developed so that the blood pressure was 16 per cent. higher than originally.

One of the objections to the use of the extract which has been injected into the series of cats already referred to is that the material injected was a coarse emulsion and that until this emulsion could be made to yield a soluble substance capable of exerting a pressor effect the results obtained could not be quite convincing. Tigerstedt and Bergman have, *however, succeeded* in obtaining a solution of the active material which can be quite freed from any granular contents. The kidney is rubbed up with absolute alcohol and filtered; the precipitate is dried in the air at room temperature and is then extracted with salt solution. One to two cubic centimetres of this extract exert as great a pressor effect as the fresh preparation; the active substance is not destroyed by alcohol. They speak of this extract as "Extract A." If it is boiled or heated in a water bath this extract loses its properties, but exposure to a temperature of from 54° to 56° C. does not apparently disturb the pressor effect. The pressor substance, to which these workers give the name of "renin," is not *dialysable.* From these various reactions it may be concluded that renin is a substance *sui generis* and that the effects produced on the blood pressure are not due to any of the crystallisable substances which are excreted in the urine. [Riva-Rocci had also failed to demonstrate a pressor effect in any constituent of the urine.] A further interesting observation was made by these workers that "renin" was present only in extracts made from the *cortex of the kidney*, and not at all or only to a slight extent in extracts of the *medulla*. A crucial test was applied by these workers by injecting blood derived from the renal vein, but, as they explain, it is hardly to be expected that by injecting two cubic centimetres of venous blood derived from the kidney, which in comparison with the extract they had prepared would contain a much smaller amount of renin, much effect would be obtained. Moreover, the blood supply to the kidney is so rich that the percentage amount of renin in the venous blood would again be considerably less than in the extract prepared from the kidney substance. These same remarks may be applied to explain my own failure to detect in the blood of patients suffering from high blood pressure any pressor quality when injected into cats with undamaged kidneys. They therefore first removed the kidneys from two rabbits one or two days before injection, thereby as it were robbing the blood of the animal of its usual amount of renin. They then injected two cubic centimetres of renal blood derived from the renal vein and were able to establish a rise of pressure of 25 per cent. in one case a minute after the injection and of 13 per cent. in the second experiment two minutes and 50 seconds after injection. From the above results Tigerstedt and Bergman suggest that *renin actually passes from the kidneys into the blood; that in the kidneys a substance is formed which under normal conditions may pass from the kidney into the blood by a process of internal secretion, and may exert a pressor effect.* A preparation of fresh extract made by rubbing up fresh kidney substance with fresh defibrinated blood was also found to be active. These two workers give a long list of all the experiments they carried out in which the nervous system was left intact and excision of the kidney had not been carried out in the animal into which the injections were made. The list includes 23 animals (rabbits) and the number of injections was 53 in all; on 50 occasions the effect on the rise of blood pressure was positive and in three cases only there was a negative effect; but it is to be observed that in each of these three cases injections had already been made with positive effects and it is known that the effects of the latter injections are frequently less marked than earlier ones. A remarkable feature of the effects of injection is the long time during which the effects last. After a somewhat rapid and transitory fall of pressure the arterial pressure begins to rise and reaches gradually a maximum within an interval of from one to two minutes. The blood pressure then sinks slowly but in certain circumstances remains for 20 minutes at a higher level than before the injection. The degree and duration of the rise are apparently independent of the amount of extract injected, except in those cases in which the amount of injection is very small, when it will be found that the rise is less than in doses which are a little larger. In repeated doses the extract exerts in some cases an effect as large as in the first injections, but in other cases, and apparently in most, the influence of the second dose is less than is that of the first one. The absolute rise of pressure in the experiments in which a watery extract was used is in general greater according as the initial pressure of the animal is lower. The experiments with "Extract A," however, show in this particular less regular effects and Tigerstedt and Bergman explain this on the ground that the "Extract A" is not always equally rich in renin and that various individual animals vary in their reaction to its effects. These two authors then proceed to analyse the effects produced. They found that the changes of pulse frequency after injection of renin are not great and it may be concluded that the pressor effects exerted by renin cannot be dependent on alterations in pulse-rate. The pulse changes are much more likely results rather than causes of the rise of pressure. Division of the cervical nerves did not interfere with the effects met with after injection of the "Extract A." Nor does it appear likely that the renin acts upon the heart, for they found that preparations which in an intact animal produce the usual effects are quite unable to show any effect on the isolated surviving rabbit's heart. Nor was it possible to attribute the effects to changes in the chief vaso-motor centre, for the effects were present when the cervical cord was cut and also when the cord was cut at the level of the fourth dorsal vertebra. Nor were the effects due entirely to action on the spinal vaso-motor centres, for destruction of the whole spinal cord by means of a sound failed to abolish the effects completely; they could not, however, exclude some possible effects due to action on the vaso-motor centres of the spinal cord, and this was shown by the fact that when both vagi were cut and an injection of six cubic centimetres of "Extract A" had been made stimulation of the right depressor nerve caused a fall of pressure. This same experiment also showed that the effect was not upon the musculature of the blood-vessels and it will be remembered that Oliver and Schäfer used this mode of experimentation to prove that extract of suprarenal substance did act on the musculature of vessels. The net result of these observations on the analysis of the effects produced by injection of "Extract A" was to show that fresh renal extracts produce rises of pressure by acting on the peripheral nerve centres as well as possibly on the spinal cord.

---

[1] Lecture I. was published in THE LANCET of May 12th, 1906, p. 12-5.

[2] Skandinavisches Archiv für Physiologie, 1898, Band viii., S. 223.

Finally, Tigerstedt and Bergman consider the question of the fate of renin when it enters the circulation normally. As already stated, under favourable conditions the rise of pressure in intact animals lasts almost 20 minutes. If, however, the kidneys are removed the pressure is raised for a very considerably longer period of time but eventually even in these cases its effect wanes. From this it may be concluded that renin is got rid of from the body partly by the kidneys but also that it is partially destroyed by the tissues or is possibly got rid of by the bowel.

I have quoted the observations made by these two workers because I think their discovery is so important to pathology not only in the study of disturbed action of the kidneys but in the study of the subject of auto-intoxication in general. So careful and so exacting have they been in their work that it is difficult to offer criticisms which would be of great weight. There are some points, however, upon which we require more information. The first is that there is no mention whatever of the anæsthetic used—whether it was of the nature of chloroform or ether or of morphine. It is therefore possible that the same criticism may be offered upon their work as upon my own—viz., that the effects were not obtained in an animal when placed under the most favourable conditions for the investigation of problems connected with the vaso-motor system. The writers expressly state that in the 23 cases in which 50 successful injections were made—*i.e.*, were followed by a rise of pressure—the nervous system was intact; presumably atropine was therefore not administered. Another point is one which is of great importance—they apparently had no failures. In one case already referred to in my own list it will be remembered that the animal failed to respond to any injection and in another respiration was so faulty without injection that the experiment had to be abandoned. In another case the injection of renal extract was followed by a very notable fall of 20 millimetres which lasted 55 seconds; in the light of Tigerstedt and Bergman's work it may be that this was due to some other influence than that exerted by the renal extract or that some change had taken place in the extract, especially as an earlier injection of the same extract in the same animal had given a rise with a maximum of 30 millimetres lasting five minutes and 50 seconds. It seemed as well, however, to endeavour to secure results under the most exacting physiological conditions possible and so a limited number of further experiments were carried out, using renal extract for injection purposes prior to the injection of any other preparation.

The analysis of these results shows that on three occasions when the experiment was carried out, as in my first series, under the influence of ether only with spontaneous respiration a fall succeeded the injection of renal extract. A fall lasted four minutes and 16 seconds and the lowest maximum pressure was four millimetres below the original in Experiment 37. In Experiment 39 the fall was a very great one and reached 50 millimetres, lasting 14 minutes at least. In Experiment 42 a similar fall of 50 millimetres occurred, lasting one minute 51 seconds; the animal used in this experiment must, however, have been under abnormal conditions, for the division of both vagi was not followed by a rise of blood pressure; variations of the distribution of inhibitory fibres in the vagi of the cat are known. In Experiment 38 ether anæsthesia was carried out as well as artificial respiration; the very anomalous result was observed that the first injection was followed by an unusual fall of 75 millimetres and the second by a rise of one millimetre.

Turning now to the results obtained when anæsthesia was procured by the administration of ether and morphine, respiration being carried out artificially, a rise of pressure followed the injection of renal extract on four occasions (Experiments 36, 38B, 41, and 42B). No rise and even a fall occurred in three experiments (Experiments 38B, second injection, 40A, and 41, second injection).

Another condition under which the injection was made was to administer ether and morphine or curari, to carry out artificial respiration, and to cut the vagi. A rise of pressure followed the injection of renal extract in three cases (Experiments 35, 38C, and 39B). A fall occurred in two cases (Experiments 38A and 40B).

These results are obviously unsatisfactory, for although the majority give some support to the view that there is a pressor substance extractable from the kidney, a good proportion of cases show the reverse. It may, however, be conceded that the much more uniform effects produced when the animal is intact and adequate anæsthetisation has been produced by ether give a better idea of the effects produced by renal substance than when various operative measures, &c., have been carried out as well. Considering the frequency with which Tigerstedt and Bergman obtained pressor results with their preparation "Extract A," it may be that further experiments carried out with this preparation under conditions of a more exacting nature—for example, anæsthesia under ether or chloroform and morphine—will give more uniform results. As already stated the two workers referred to do not say what anæsthetic was used and it is not very clear how they prepared "Extract A," for the amount of absolute alcohol added to the original kidney substance is not mentioned nor is reference made to the amount of saline solution with which the dried residue was rubbed up; it was surmised that for the preparation of "Extract A" five times as many cubic centimetres of absolute alcohol should be added to the kidney pulp as there were grammes of that substance. The residue left after the removal of the alcohol in a desiccator was rubbed up with a 1 in 3 saline solution.

Pressor substances have been demonstrated in the suprarenal medulla and in the posterior lobe of the pituitary body and there has been abundant confirmation of the results. The pressor effect of kidney substance was obtained ten years ago by Tigerstedt and Bergman and the results have been quoted so largely by me because the work is so exhaustive nd thorough. Oliver[3] has published his results of the action f animal extracts on peripheral vessels. He made observaons on the mesenteric vessels of the frog before and after he application of normal saline solution used as a control nd normal saline solution containing 1 per cent. of the xtract of an organ dried at 38° C., the temperature being he same for both solutions. Any change of calibre was ccepted as the effect of the extract when it exceeded he normal variations and when it was practically *imnediate*, was invariable, lasted a certain fairly uniform time nd was succeeded by restoration of calibre. Observations were made with the brain plugged and with the brain and ord destroyed. Oliver found no *invariable* change given by the use of extracts of liver, pancreas, kidney, or brain; a moderate constrictive effect, however, was obtained so far as the experiments had been carried out with extracts of spleen, testis, and pituitary gland. Suprarenal extract was found to produce a marked constriction which persisted for from 30 to 60 minutes.

The work of Tigerstedt and Bergman has, so far as I can gather, not been repeated except in the particular of the pressor effect of blood drawn from the renal vein. Tigerstedt and Bergman carried out but two experiments with the blood drawn from the renal vein of a rabbit, injecting it into the veins of another animal; the pressure rose in both cases. Lewandowsky[4] approaches the question of the alleged internal secretion of the kidney as suggested by these experiments and points out that controls were not made. He experimented on seven animals; in one the kidneys had been extirpated 24 hours previously, in one 72 hours, and in the remaining five 48 hours. He injected renal vein blood and used controls in each experiment, injecting blood abstracted from the jugular vein. In all cases the blood was injected into the jugular or facial vein of another animal. The result was that the injection of renal blood gave an effect differing in no way from that of the blood derived from the body as, e.g., out of the jugular vein. In three cases, however, there was a rise of pressure which was not inconsiderable but Lewandowsky concludes it was not a specific rise, for the controls injected with jugular blood also showed a rise. He considers that in part this rise was due to the rapidity of injection but admits that similar masses of saline solution injected under similar conditions were quite incapable of causing such a rise *and concludes that in defibrinated blood substances are present which under certain conditions can cause a rise of blood pressure.* Lewandowsky pursues this problem no further, but ends with a criticism of this part of the work of Tigerstedt and Bergman and denies that the renal blood exerts a specific pressor effect. Whatever may be the verdict as to the value of these observers' two experiments in showing that there is an internal secretion in health, no one can doubt that the significance of their experiments with the renal cortex for pathology is very great. The one thing we should like to know, however, is whether or not other fresh tissue produces a rise of pressure; from the experiments I have made it seems possible that they can do so, but it can be said that brain tissue did not do so, spleen substance only occasionally, and that liver in a very large proportion of cases did not cause a rise of pressure. In the latter case the presence of bile in the tissues causes a difficulty, for it is known that bile salts of themselves cause a fall. So, too, urine causes a fall and if this is not well washed out from the kidney it may be the cause of some of the negative results following an injection of kidney extract. Reasons will be given later to show why brain extract causes a fall of pressure.

We have already seen that 11 out of the 12 patients in whom there was a rise of blood pressure above normal limits had obvious signs and symptoms of renal disease. In the four fatal cases amongst these 11, sclerosis of the kidney was present; in three the *cortex* was *shrunken*. We know that the tonus of the musculature of the blood-vessels is under the influence of reflex stimuli which act through all centripetal nerves and also through an automatic mechanism—that is, through the depressor nerve, which, giving warning when the intracardiac pressure is abnormally high, leads to a fall of pressure through the influence exerted on the vagus and vaso-motor centres. It is through this latter mechanism alone that all those substances which arise normally in health through the disintegration of body tissues, &c., can possibly act on the blood pressure. In disease it is reasonable to believe that in some cases some substances act more markedly upon this automatic mechanism which includes the musculature of the blood-vessels.

The question that now presents itself is this, Can we derive from the discovery of Tigerstedt and Bergman any explanation of the pathological departures which we have already noted as occurring in blood pressures at the bedside? The answer must be that there is good reason to think that they have added a great deal to our knowledge because, so far, no one has been able to associate the alterations met with in the blood pressure in renal disease with any definite cause. If the renal cortex contains a pressor substance capable of causing rise of pressure then, when it enters the circulation which it is reasonable to believe may occur in certain pathological conditions, blood pressure rises.

Tigerstedt and Bergman rightly adopt a most modest attitude towards both the physiological and pathological bearings of their discovery. They have comparatively little to say about the physiological effect of renin upon the circulation and their wisdom is apparent at once, for although it is well known that the cells of the organ are constantly being replaced by new ones, the old passing through a series of changes, to which I will refer presently, preparatory to being removed from the body, it is certainly not satisfactorily proved that such cells in the early stages of their bio-necrosis are capable of being used for the maintenance of physiological arterial tension. But there can be no doubt whatever that when this possibility is transferred to the arena of pathological discussion a very different reception must be accorded to it. We know that in the contracted kidney one of the best established changes is the shrinkage of the cortex, which has been shown to contain more renin or pressor substance than the medulla.

It is acknowledged that high arterial tension is not so constant a feature of chronic parenchymatous nephritis as of the interstitial variety, but still it does occur. It is, however, very common in cases of renal sclerosis. Possibly hypertension is an expression of a kidney condition in which renal parenchyma, little altered or not at all, is passing into the circulation either from changes, as in contracted kidney, associated with obliterative arterial disease or as a result of toxic agents which are more common causes of parenchymatous changes. In cases of severe acute nephritis observations have been made with the sphygmomanometer which show that hypertension also occurs and even may do so within 24 hours from the onset of the kidney lesion. Buttermann[5] found a rise of blood pressure in the majority of 18 cases of acute nephritis; in 13 cases of granular kidney the pressure was *always* raised and in the cases which proved fatal there was *always* a condition of contracted kidney and hypertrophy of the heart; in 13 cases of chronic parenchymatous nephritis pressure was raised in one-third of the cases, in the rest it was normal or subnormal. In three early cases of lead poisoning the pressure was normal. The older observations of Traube and Riegel without the syphgmomanometer also point to the possibility of a rapid rise in arterial pressure in the nephritis of scarlet fever. It therefore seems probable that in view of Tigerstedt and Bergman's discovery and of the inadequate nature of the older mechanical views of the causation of cardiac hypertrophy and of hypertension (Cohnheim, Fagge, and Thoma) maintained hypertension may mean liberation of kidney substance and its entrance into the circulation. Whatever the blood pressure may have been beforehand, if a toxic agent leads to the liberation of sufficient renal parenchyma, or if a sufficiently large district of renal tissue is newly cut off from the general circulation by extension of occlusive disease already affecting the renal vessels, the cells involved yield a pressor substance to the system and cause a rise of pressure above normal. If the liberation is small then there may be little or no disturbance of the blood pressure already existing.

It is well known that sclerosis of the kidney may be found unexpectedly in post-mortem examination, no symptoms ever having apparently called for relief. In other cases uræmia develops quite suddenly in patients previously apparently quite healthy. It is quite conceivable that some of the cases which are now being recognised as cases of increased arterial tension, largely owing to the help of the sphygmomanometer, without any signs of renal disease or of disease of the superficial arteries, are really cases similar to those just mentioned; liberation of renal tissue may be taking place and only show itself clinically by the production of increased pressure and by signs which are so slight as to be disregarded or so equivocal as to defy interpretation. Such cases would be included in the group of angio-sclerosis and of pre-sclerosis described by von Basch and by Huchard. Even the cases of hyperpiesis described by Professor Clifford Allbutt may be of similar nature. Extravagant claims must not be made, however, for the discovery of Tigerstedt and Bergman; hypertension must not in the present state of our knowledge be referred to a nephræmia alone; it is possible that other tissues when once freed from accompanying disturbing factors, such as contained excretory matter, &c., will be subsequently shown to produce as constant pressor effects as kidney substance does. Hypertension may be shown to exist in conditions in which other organs than the kidney are undergoing disintegration; in my cases there is no evidence to show that clinically hypertension maintained for a considerable time exists except in cases in which the kidney is affected.

[4] Zeitschrift für Klinische Medicin, 1899, Band xxxvii., S. 541.

[5] Deutsches Archiv für Klinische Medicin, 1902, Band lxxiv., S. 1.

In the list of clinical cases referred to in the first lecture reference was made to the fact that in four of the cases of high tension the patients died and renal sclerosis was found in each of them. *Uræmia was present in all these cases;* the blood pressure was raised above normal till within a few hours of death. Hypertension is considered to be a feature of uræmia[6] and this short list confirms this view. The idea has been advanced that in uræmia a poison is developed which provokes arterio-spasm (Traube), and as a result of this condition such cases frequently present symptoms of mono- or hemi-plegia and yet post mortem no lesion can be found to account for such signs. This difficulty was met with in the first of the clinical cases referred to in the first lecture. Here, again, the power possessed by the renal cortex of producing spasm of the arterial musculature gives support to the view that uræmia, a condition which so far has eluded all satisfactory explanation, may be due in part at least to an abnormal or excessive amount of pressor substance derived from the kidney cells. The view that the vessels of the brain may be contracted by the action of liberated renin is rendered tenable by the more recent observations which show that the cerebral vessels possess a nerve supply. There is no difficulty in attributing the various acroparæsthesiæ, &c., which usher in uræmic manifestations, to arterio-spasm, such as could be induced by the escape of renal tissue into the circulation.

That the blood pressure does not remain high in all cases of uræmia till death occurs does not militate against this renal origin of uræmia because with the suppression of urine which so often occurs there is a retention of material which is able to act as a cause of lowered arterial pressure and, moreover, as will be seen subsequently, one of the results of deep disintegration of tissues in general is to produce substances which cause constantly a fall of pressure.

Just as in the case of hypertension all workers look forward to the discovery of a toxic cause, so, too, in uræmia, the same hopeful anticipations have been made; indeed, some have gone so far as to insist that the toxic cause is an albuminous one. We know that the retention theory is a quite inadequate explanation of uræmia, that the theory that uræmia is due to a failure of the internal secretion of the kidney is also not proven, and that though we possess certain knowledge that ablation of kidney substance causes experimentally a loss of a check upon the rapidity of proteid disintegration and therefore favours an excessive formation of urea, especially in the muscles, such experiments have not given us knowledge of the cause of uræmia (Dr. J. Rose Bradford). But there is reason to believe that Tigerstedt and Bergman, by showing that the renal cortex when once it enters the circulation causes spasm of the arteries, have demonstrated a toxic agent, such as has been invoked by Traube, to complete his hypothesis that arterial cramp is responsible for some at least of the features of uræmia. If we invoke the results of treatment we find that this view is supported, for we know that renal asthma so-called, which is so often met with in sclerosis of the kidney, is able to be greatly remedied by the use of drugs which dilate the arteries. It will be remembered that some of the clinical cases showed extreme hypertension and yet were free from uræmia—e.g., Case 2. It is therefore necessary to invoke some local factor and this may be found in the effect produced by arterial disease; the lumen of a vessel the seat of arterial disease may be large enough to admit sufficient blood in ordinary circumstances, but when once arterial spasm is added as well, the blood passing to any particular organ or district becomes inadequate and hence possibly some at least of the uræmic manifestations. In short, it may be that some of the signs of uræmia are dependent upon a sort of "intermittent claudication" or rather "paroxysmal claudication" of certain vascular areas and that renin may be the immediate cause and local vascular disease a predisposing one; given the absence of either of these factors uræmia may not result, but it is possible to believe that the arterial spasm produced by renal pressor substance may in some cases be sufficient in itself to cause some of the phenomena of uræmia; that this is possible is to some extent shown by the fact that uræmia is not always fatal (Case 9), recurring several times, and occlusive vascular disease may not be demonstrable in all cases.

You will probably, as a result of this suggestion that uræmia is due to the effect of a toxic substance derived from the renal tissues capable of producing arterial cramp, &c., raise the point that Dr. Bradford, and subsequently Dr. Herringham, Dr. Griffiths, and other observers, have published records showing that the cortex of the kidney may be in a condition of acute necrosis and yet uræmia is absent and death occurs in six or seven days, the dissolution being more like that met with in obstructive suppression than in non-obstructive suppression of urine. It may well be thought that such cases would constitute good tests of the correctness of the above view. Unfortunately, at the time such cases were observed blood-pressure observations by means of the sphygmomanometer were not made. However, uræmia was absent and yet the cortices of the kidneys were necrosed. There is but one answer to make to this apparent refutation of the above theory—viz., that the arteries of the kidney cortex were completely thrombosed; the cortex was in a condition suitable for the causation of high blood pressure and possibly of uræmia but the vascular occlusion was too complete to allow of the cortical substance gaining access to the circulation.

That obstructive suppression due to impacted stone, &c., does not cause the signs of uræmia to appear is explainable on the ground that the normal urinary constituents in not being able to escape from the body are capable of causing a fall of blood pressure.

Hypotension.—A consideration of the list of 68 clinical cases not only showed the existence of a group of patients in whom high arterial tension was a feature but also a number in whom low pressure was present. The same method of answering the problem of the cause of low pressure has been adopted as in examining for the cause of high pressure. Even quite fresh liver and brain, as a rule, caused a fall of pressure, so that it is conceivable that in diseases affecting these organs—such as cirrhosis of the former and softening of the latter—material is directed into the circulation and produces similar depressor effects. But the problem at once occurs, Is it at all likely that different effects are produced upon the arterial tension according to the degree of altered nutrition which exists in various organs in different diseases or in different stages of such diseases? To answer this problem satisfactorily a digression must be first made in the direction of studying briefly the chemistry of the products of decomposition of the cell body and of its nucleus. Such a task, however, requires the consideration of a phenomenon which has excited considerable interest and which was first seriously studied by Professor E. Salkowski. I refer to the subject of auto-digestion—i.e., a process in which the cell contents undergo liquefaction owing to their removal from the body and so from their natural sources of food-supply and from those means by which the products of their solution are able to be removed. Hoppe-Seyler in 1871 made the following statement: "All organs dying within the interior of the organism undergo, in the absence of oxygen or even in its presence, liquefaction; during the progress of softening leucin and tyrosin are formed from proteid and free acids or soaps from fats. The phenomenon is accompanied by no development of offensive odours and may be compared with the processes which are associated with the action of digestive ferments." Although these observations were made so long ago that the exclusion of bacterial effects could not have been considered, more modern work has proved the correctness of the view that tissues are able on their own account to liquefy.

---

[6] Ascoli: Vorlesungen über Uraemie (Jena, 1903). (I am indebted to Dr. A. E. Garrod for drawing my attention to this work.)

Hüfner, in 1872, made a discovery which brought the explanation of this process much nearer solution. He found that after extracting the salivary glands of the pig and the lungs of calves by means of glycerine it was possible by precipitation with alcohol to obtain a substance which differed very much from proteids and was able to digest proteid. Thus, digestive ferments appeared to be widespread in the system. It was, however, objected that such processes were entirely post-mortem changes and that they had no representation in the living body—a somewhat singular attitude to adopt, for it is hardly to be expected, as Salkowski says, that when life ceased in the individual such a vital phenomenon as digestion of tissues should only then be initiated; it is much more likely that the processes operating after death are also active during life. Differences exist, of course, in the two conditions, for in life the primary dissociation products are removed but in the dead body such products remain *in situ*.

Salkowski,[7] as a result of the observations made by Hoppe-Seyler and Hüfner, was able to conclude that proteolytic ferments occurred not only in the digestive tract but also were present throughout the body and though weak agencies were necessary to the organism, for they were found in the lowest forms of life. Thus was laid the foundation of our belief in what is now known as auto-digestion or autolysis by means of intracellular ferments—a process which is of importance not only in the study of metabolism in health but which has important bearings on various pathological problems. Schützenberger followed with his observations on the power of yeast to digest itself. Yeast was placed in water for from 12 to 15 hours at a temperature of from 35° to 40° C.; considerably less yeast was found to be present at the end of the experiment than if it had not been exposed to warmth; part of the yeast had evidently gone into solution, because the watery extract of the incubated yeast was found to contain leucine, tyrosine, carnine, xanthine, guanine, and hypoxanthine.

Salkowski, impressed with the probability that intracellular ferments existed in life and were responsible for intra-vital autolysis, made observations on the liver. He prepared the liver by mincing it and placed it in chloroform water. Flasks of this mixture were exposed to a temperature of 40° C. for from 60 to 70 hours and were frequently shaken—"antiseptic" autolysis. The mixture was shown to be sterile at the end of the incubation and control observations were made by boiling before incubation. Salkowski prefers to use chloroform as an antiseptic because of the ease with which it may be driven off from the preparation when no longer required. Toluol has been used by other workers in preference to chloroform: the latter antiseptic is known to prevent not only bacterial development but as with toluol the action of unorganised ferments is also somewhat inhibited by it. Toluol appears, however, to have a great drawback in that putrefactive changes have been known to go on even in its presence. Analysis of the two preparations made by Salkowski showed that as a result of antiseptic autolysis there is a considerable increase of soluble organic substances and this is notably the case in regard to the nitrogenous bodies. The increase of soluble nitrogenous substances is due to the formation of primary dissociation products derived from proteids and nucleo-proteids.

It is well known that the animal cell contains proteids in the cell body which also to some extent prevail in the nucleus and that the nuclei contain various nucleo proteids. Recent investigation[8] in chemical physiology has been directed largely towards an elucidation of the cleavage of proteids and nucleo-proteids. These former bodies may be split by various agencies such as heat, acid, alkalies, and bacteria and then give rise to what are known as "primary dissociation products." But the same dissociation which is a process of hydrolysis, being associated with the breaking up of water and the incorporation of the liberated hydrogen and oxygen, occurs in digestion of proteids and derivatives by the ferments pepsin, trypsin, erepsin, and arginase. The first two, especially trypsin, are instrumental in simplifying the proteids by producing albumoses and peptones, but also are able, though at a much slower rate of velocity of action, especially in the case of pepsin, to exert those deep disintegrations of proteid derivatives which are special duties of the erepsin and arginase, ferments which are present not only in the intestinal mucosa but also in the tissues of the body, erepsin being almost universally distributed and arginase being found especially in the liver.

The primary products of proteid dissociation include at least four different groups of bodies. Amongst the best known substances are leucine and glycocoll (mono-aminic acids); in the same group occur alanine, asparagine, aspartic acid, glutamic, and amido-valerianic acids. A second group consists of three members which are known as hexone bases because they contain six carbon atoms; they are known as lysine, arginine, and histidine; they have the common feature that they are formed by the introduction of two amino-groups into fatty acids. A third group of primary dissociation products includes derivatives not of fatty acids but of the aromatic series, and the best known is tyrosine; one which has recently been much investigated is tryptophane and another is phenylalanine. A final group includes ammonia, which by the action of ferments can be split off from the proteid molecule directly; also the sulphur-containing substance cystine, scatole, indole and the pyrimidine bases, such as thymine and cytosine. It is probable that between the group of somewhat simplified proteids such as proteoses and peptones on the one hand and the bodies indicated in the above four groups on the other, there exists a group of substances which are intermediate in character and consist of groupings together of various amino-acids: these are known as polypeptides. A number of dissociation products exist but at the present time it is impossible to say whether they are primary or derived by disintegration of other primary bodies; amongst these bodies may be mentioned leucinimide and hydrocyanic acid.

The number of secondary dissociation products capable of arising by the action of hydrolytic ferments upon primary dissociation products is limited. It is known that the amino-acids above mentioned are very resistant to the action of pepsin and trypsin; desamination, or the attack upon the amine constituent in amino-acids, is not a strong feature of peptic or tryptic action, but other ferments are present in the body and are capable of exerting this lytic action, for amino-acids when given in moderate quantities are completely broken up—e.g., glycocoll, alanine, leucine, and phenylalanine. When once amino-compounds are converted into imino-compounds then trypsin, erepsin, and arginase are capable of attacking the imino group.

Important as the study of the decomposition products of proteids may be for a thorough comprehension of the important observations made by Salkowski on autolysis, still greater importance is attachable to the study of the nucleo-proteids which enter so largely into the composition of the nucleus of cells in consort with glyco-proteids.

Nucleo-proteids.—The nucleo-proteids are widely diffused in the animal body and form important constituents of all nuclei. It is known that on the destruction of the cell derivatives of nucleo proteids are capable of passing into the body fluids and have been found in the blood. They are strong or weak combinations of proteids and various nucleinic acids. Nucleo-proteids yield all the ordinary dissociation products which result from the disintegration of proteids, and in addition they yield pyrimidine derivatives, purin bases and phosphoric acid, as derivatives of the nucleinic acid.

The purin derivatives.—Fischer has indicated by the term "purin" a nucleus having the composition expressed by the formula $C_5H_4N_4$; bodies constructed on such a foundation are spoken of as purin or alloxuric or xanthine bodies. Amongst the best known of these are hypoxanthine, xanthine, uric acid, guanine, and adenine. Just as in the case of the derivatives of proteids, observations have been made on the toxic effects produced by the introduction of such substances into the economy, so also the derivatives of nucleo-proteids have been studied with the same object. By studying the effects on blood pressure of some of these derivatives, it is possible to draw some conclusions as to the possible causes of those interesting cases or occasions of depression of blood pressure which were noted in the list of clinical cases already referred to; the importance of such study is well shown by the knowledge that life is impossible when the blood pressure falls below a certain minimum.

THE CHEYNE-STOKES PHENOMENON IN ACUTE CEREBRAL COMPRESSION.[1]

BY WILFRED TROTTER, M.S. LOND., F.R.C.S. ENG.,
DEMONSTRATOR OF ANATOMY IN UNIVERSITY COLLEGE, LONDON;
LATE SURGICAL REGISTRAR, UNIVERSITY COLLEGE HOSPITAL.

THE group of periodic manifestations often referred to as "Cheyne-Stokes respiration" is met with in surgery chiefly as a symptom of cerebral compression, and as a rule is not regarded as being of more than slight practical importance. In surgical writings it is generally described as a terminal condition and therefore of very grave significance in prognosis, while attention is not usually directed to any interest that it may have in diagnosis or to any evidence that we possess as to its causation. Each of these three aspects of the phenomenon will be briefly discussed in this paper.

DEFINITIONS.

As the subject of these periodic phenomena has been somewhat confused by purely verbal ambiguities, some preliminary attempt towards definition has been rendered desirable. In the first place, the phrase "Cheyne-Stokes respiration," or any name in which the word respiration occurs, is unsatisfactory, as it is a matter of common experience that the respiratory manifestations may be absent. Again, many writers maintain a distinction between what is called the true Cheyne-Stokes respiration and the so-called cerebral respiration. The latter is often named after Biot who called attention to its peculiarities in 1876 and laid great stress on its differences from the Cheyne-Stokes type. The Biot type of respiration differs from the Cheyne-Stokes solely in showing abruptly limited groups of respirations with no gradual waxing and waning—that is, the former presents an abrupt alternation of hyperpnœa and apnœa, while the latter shows apnœa alternating with hyperpnœa by a gradual transition and the reduction in the amplitude of the breaths may never reach true apnœa. As this distinction is not absolute, for many transitional forms unite the two types, its maintenance is not of much value. That, however, there is a type of grouped respiration occurring in cerebral cases which Biot was justified in distinguishing absolutely from Cheyne-Stokes breathing there can be no doubt. This is the form of irregular gasping respiration which occurs in the late stages of cerebral compression when the vaso-motor centre has already begun to fail and the blood pressure is rapidly falling. This is a true terminal manifestation and is associated with other evidences of a failing circulation such as pallor and a weak irregular pulse. It presents a fundamental difference from Cheyne-Stokes respiration in its irregularity both in its occurrence and the number of breaths in each group. Such a symptom is, of course, almost necessarily of fatal significance, for it is in essence a condition identical with the gravest kind of shock and could only be met by efforts directly to raise the blood pressure independently of the centre by such means as the intravenous injection of adrenalin and by mechanical compression of the peripheral circulation. Three conditions, then, are recognisable—two, closely associated, of true periodic breathing differing only in the way in which the transition from hyperpnœa to apnœa is effected, and a third, essentially different from both, depending upon vaso-motor paralysis. For the first two there is no satisfactory inclusive name. At present when our knowledge of their pathology is so imperfect the clumsy phrase "Cheyne-Stokes phenomenon" is perhaps the least objectionable.

CLINICAL FEATURES.

No detailed description of a condition so familiar as is the Cheyne-Stokes phenomenon need be given here. It is enough to enumerate the four chief factors in the group and shortly to comment on them. In the fully developed form the following factors are recognisable. (1) Periodic respiration; (2) variations in pulse-rate and strength and in the blood pressure; (3) variations in the size of the pupils; and (4) variations in consciousness. It should be understood that these observations refer only to the Cheyne-Stokes phenomenon as it occurs in cases of cerebral compression.

1. *Respiration.*—As already said, regular periodicity is the principal characteristic. Two extreme types are seen—the gradual and the abrupt transition between hyperpnœa and apnœa. Intermediate forms occur such as an abrupt beginning and a gradual ending of the hyperpnœic period and *vice versâ.*

2. *Circulatory variations*—Increased strength of the pulse during hyperpnœa is the most important feature. Increase in the pulse-rate is usually observable at the same time. Increase in the blood pressure has also been recorded (Cushing) but such observations must obviously be open to fallacy when made with the Riva-Rocci apparatus on account of the increased muscular tension during the hyperpnœic period. The record would only be unobjectionable if the observations had been made on the paralysed side in a case of cerebral compression. In the only record I have found this point was not noted.

3. *Variations in the pupils.*—The pupils dilate just before or at the onset of the hyperpnœa. This variation is not uncommonly absent and for it to occur the pupillary light reflex must be present.

4. *Variations in consciousness.*—In my experience of cases of cerebral compression showing the Cheyne-Stokes phenomenon the patient has always been unconscious. This is probably not a necessary concomitance but rather an expression of the fact that the compressing agent in the majority of cases compromises the cerebral hemispheres first, while compression primarily affecting the bulb rapidly passes through the period when the manifestation of the Cheyne-Stokes syndrome is possible to the production of a fatal paralysis. Were traumatic compression of a slight grade commonly primary in the cerebellar chamber periodic breathing with full consciousness during the hyperpnœic periods would probably be as common in cases of head injury as it is in disease. In actual experience in such cases during hyperpnœa the decrease in the profundity of the unconsciousness does not reach complete consciousness. The most that is attained is a state corresponding with the well-known second stage of cerebral compression of Kocher, or stage of irritative manifestations. The patient then displays restlessness and certain peculiar movements of the limbs, and, rarely, a paralytic manifestation, such as conjugate deviation of the head and eyes, may for the time disappear. (See Case 2.) He groans and mutters and may fumble in a semi-purposive way with things put into his hand. Of this group of phenomena the peculiar movements of the limbs are the most striking and important. These are no mere irregular jerkings of the limbs such as occur in a steadily maintained irritability of the cortex. The periodic return of function is associated with a fixed result, so that during each period of hyperpnœa a complex and stereotyped series of movements occurs. At or before the beginning of the group of respirations the arm begins to execute such actions as scratching or rubbing, pulling the moustache, and so forth. The movements are always complex, they have the appearance of being voluntary, and are such as might be expected to be habitual. They are, however, performed through hundreds of repetitions in an exactly similar order and with an unvarying preciseness of reproduction. If an attempt is made to interfere with them they are persisted in with considerable force, the hand struggling with the restraint, and if successful completing the series unless apnœa should have meanwhile intervened. If the hand in its wanderings encounters anything the latter is fumbled with, often in such a way as to show recognition; if an unfamiliar object is met with such as a bandage round the head, the hand will often pluck at it and even succeed in tearing it off. In the leg the movements, as might be expected, are much simpler and usually confined to mere flexion and extension. A very important fact is that when a part of the brain is involved to the extent of producing anæmia and therefore paralysis of the limbs supplied by that region, such limbs will not be moved during the hyperpnœic periods. As already stated, it is only in rare cases that a true paralytic symptom disappears during those periods. The onset, then, of a hemiplegia can be watched

---

[1] Part of a paper read before the Medical Society of University College, London, Jan. 17th, 1906.

by noticing the gradual cessation of the Cheyne-Stokes movements in the limbs involved, while those of the opposite side continue to move strongly.

Certain modifications of the classical type of the phenomenon are very common. It may be said broadly that any one of the four factors may be absent and quite often more than one. The pupil changes are perhaps the least constant; the respiratory periodicity is quite often absent, especially in the earlier phases of the case. The periodic movements are probably the most constant feature. This great variability is possibly the reason why the Cheyne-Stokes phenomenon, though very common in cases of head injury, has excited comparatively little the interest of surgeons.

DIAGNOSTIC SIGNIFICANCE.

The value of the phenomenon in diagnosis is perhaps its most important feature. In the first place, as we shall see later, it affords certain evidence of severe compression of the brain and of implication of the bulb which, if left unrelieved, will surely cause death. It is not, however, an immediately terminal symptom, for it may persist in its fullest development for many days and it indicates a modified functioning rather than a paralysis of the medulla. Secondly, it may give rise to difficulties in diagnosis through the periodic movements being taken for evidence of focal irritation. We have already seen that the movements will be absent from a hemiplegic side; it is therefore obvious that if the movements be taken as pointing to a focal irritation the side of less advanced compression—that is, the side opposite to the hæmorrhage—will be operated on. The movements occur in groups and when they are unilateral do, in fact, present some superficial resemblance to those of a fit. Such a mistake is, of course, easily avoidable and is rendered impossible by the following considerations. 1. The Cheyne-Stokes movements occur at regular intervals and last for regular periods. Between attacks there is complete cessation of movement. 2. They are of wide range and complex character and in spite of their complexity are repeated time after time with great exactitude. In one case, for example, the patient rubbed the side of his face, chest, and abdomen in that order at regular intervals for a great many hours. The limb shows signs of mere fatal automatic action and accommodates itself to some extent to new circumstances; this can be seen if some object is put into the hand or an attempt is made to control the movement. In rare cases one may see on one side the complex Cheyne-Stokes movements and on the other the simpler ones of a fit. 3. They begin simultaneously throughout the limb and affect the arm and leg together, showing no trace of the orderly march of a Jacksonian fit. 4. They correspond with the occurrence of the other Cheyne-Stokes factors, though the possible absence of some of these factors should be borne in mind.

The third point of diagnostic interest in connexion with the phenomenon is the fact that it may reveal the presence of a paralysis otherwise unsuspected or in need of confirmation. It may be stated definitely that if Cheyne-Stokes movements are present and a limb does not participate in them that limb is paralysed. In a case of head injury this will, of course, indicate the site of maximum compression. Such an indication is of especial value in traumatic compression where there is usually evidence of widespread irritation which is apt to prove confusing.

I recall a case, not, however, of head injury, where the capacity of the Cheyne-Stokes movements of, as it were, dissecting out the paralysis was well shown. An infant had become comatose from intracranial pressure; there was nothing in the signs to distinguish definitely between tumour of the brain and meningitis—in fact, the former was on the whole thought to be the more probable. Then periodic phenomena developed with the characteristic movements. These movements, however, left unaffected the arm of one side and the leg of the other, thus affording evidence of multiple paralysing lesions and strongly suggesting the diagnosis of meningitis, which was confirmed post mortem.

The two following cases of traumatic compression illustrate most of the characteristic features of the Cheyne-Stokes phenomena to be seen in this condition.

CASE 1.—The patient, who was a middle-aged man, was admitted to University College Hospital some years ago when I was a house surgeon. About a quarter of an hour before admission he had been thrown from a cart and had pitched on his head. He was bleeding from the right ear and showed signs of concussion. Half an hour after admission he vomited and recovered consciousness. An hour later, having been very restless throughout that time, he vomited again and had a fit which began on the left side and spread to all the other limbs. With the onset of the fit he lost consciousness. After the fit there was rigidity of all the limbs and for a short time slight rapid twitching of the right side of the face. Throughout the following night he was very restless, moving about in bed and trying to pull off the bandage round his head. It was noticed that he moved the left side much more than the right and that he was quite quiet at times, but not whether there was any definite periodicity in the restlessness. The following morning he was still unconscious. Both knee-jerks were exaggerated, the right slightly in excess of the left. The pupils were equal and reacted to light. At intervals there were complicated movements of the left arm—scratching and rubbing the left side of the face and body. The movements were practically identical at each repetition and were executed with a great air of purpose. They coincided with other periodic phenomena of the true Cheyne-Stokes type. The right arm scarcely moved at all. The lower limbs were rigid. The left leg showed flexion and extension movements during the hyperpnœic periods. For the next three days the unconsciousness and the periodic phenomena persisted. The pupils continued to be equal and to react to light. Gradually all movement on the right side ceased, the limbs on that side being rigid and motionless. The limbs on the left side continued to move during the hyperpnœic periods. From the first painful stimuli applied to the left side caused responsive movements much more readily than when applied to the right. On the fourth day the rigidity had disappeared from the right side and painful stimuli applied to the right arm only caused a much delayed responsive movement of the left arm. The periodic phenomena still continued. There was no response to stimulation of the right leg. The patient was trephined on the left side and four and a half ounces of clot were removed from between the dura mater and the skull. The brain expanded rapidly and the periodic phenomena ceased. Later, however, the pulse failed and the patient died six hours after the operation. The temperature had been rising for three days and at death was 106·4° F.

This case illustrates well the early onset and long duration of the Cheyne Stokes phenomenon. It shows also the gradual onset of a hemiplegia as seen in the slow cessation of the periodic movements on the right side, followed by a period in which rigidity persisted and then flaccidity. In this case the distribution of the movements was the principal localising sign. The absence of paralytic pupil changes allowed variations of the pupil to occur with the respiratory periods.

CASE 2.—The patient, a man, aged 41 years, was admitted to University College Hospital on Dec. 18th, 1904. Two hours earlier he had received a bullet wound in the head. On the right side, about one inch in front of the external auditory meatus and two and a half inches from the middle line, there were a bullet wound of the scalp and a perforation in the underlying skull. The edges of the wound were blackened but there was nothing to show whether the bullet had been directed forwards or backwards. No exit wound was present. The patient was pale and quite unconscious and did not respond to any stimulation. The pupils were of moderate size, equal, and reacted to light. Respiration was almost inaudible and very shallow. The head and eyes showed a slight deviation to the left but were fixed in the mid position during the movements described below. From time to time at fairly regular intervals movements of the left arm occurred. They were complex in character, so much so as to suggest consciousness. During the movements the patient unbuttoned and buttoned his waistcoat, pulled his moustache, and felt and fumbled with anything his left hand encountered. At the same time there were movements of flexion and extension of the left lower limb. Careful examination showed the movements to be associated with slight increase in the pulse rate and the size of the pupil. There was no marked periodicity in respiration but careful listening revealed a slightly deeper catching breath at the beginning of the movements. As a rule the right arm and leg were absolutely motionless but now and then flexion of the fingers and adduction of the thumb were noticed. They seemed to coincide in time with the periodic movements on the other side, but were not observed often enough to allow one to infer any causal relation in the coincidence. All the limbs were rigid. The knee-jerks were much exaggerated, perhaps the right a little in excess of the left. Well marked ankle clonus and extensor response were present on the right side; on the left side there were flexor response and no ankle clonus. Triceps and supinator jerks were brisk and equal. In this case to a very superficial examination the situation of the wound and the movements on the left side might have suggested a lesion on the right side of the brain causing fits. The Babinski's sign and the ankle clonus on the right side showed, however, that there was some grave lesion of the left motor path. That the movements were periodic and not in the nature of convulsions was clear and showed that there was a hemiplegia on the right side and none on the left. The diagnosis made therefore was that there was probably no serious lesion on the right side of the brain but a large one on the left, probably within the brain substance. The bullet wound on the right side was explored and some loose fragments of bone were removed. No blood clot was found and the brain, which showed a small puncture, did not bulge. The skull was opened freely in the left parietal region. The brain showed a pronounced bulging but exploration of it failed to reveal the bullet or any blood clot. During the operation the respiration became markedly periodic with sudden transitions from apnœa to hyperpnœa. The patient died the next day; the symptoms had not been relieved and the temperature had risen to 106° F. Post mortem the track of the bullet was found to pass downwards, backwards, and to the left, missing the right motor path. It traversed the left lateral ventricle and neatly divided the posterior part of the left internal capsule. The bullet had come to the surface on the inferior aspect of the temporal lobe where it lay against the skull amidst a considerable amount of subdural blood clot.

The case corresponds with Case 1 in showing a very early onset of the periodic phenomena and the absence of paralytic pupillary changes. It is noticeable here that at first there was only very slight and easily overlooked respiratory periodicity, which later, however, became very well marked. It is perhaps worth remark that the case illustrates well how completely the dural septa may limit compression to one chamber of the skull. When the right side was opened the intracranial tension was practically normal. Immediately after, however, the left cerebral chamber showed a very high tension, a fact due no doubt to plugging of the opening of the falx by the dislocation of the left hemisphere. This mechanism and a similar occurrence in the case of the tentorium were pointed out by Hill in his classical lectures on the cerebral circulation.

PATHOLOGY.

In the very large literature concerned with the pathology of the Cheyne-Stokes phenomenon, the significance of the facts of traumatic compression in relation to the problem seems not to have received so much attention as it deserves. For this reason an attempt will be made here briefly to discuss this aspect of the matter. Such discussion must for the sake of clearness necessarily involve the repetition of certain familiar facts.

In the first place, it is necessary to base all such discussion upon the obviously fundamental proposition that all the symptoms of compression of the brain by blood are due to interference with the circulation in the brain. This circulatory disturbance is progressive and its progress is conveniently described in the three stages defined by Kocher in his work upon cerebral compression. These three stages are as follows: 1. The stage of compensation. In this period the effect of the encroachment upon the cranial cavity is merely to cause a partial compression of the larger veins and an escape of cerebro-spinal fluid, without producing functional interference with the brain or, therefore, any symptoms. 2. The stage of venous congestion. Further compression causes interference with the venous outflow, congestion and consequently an increased excitability of the cortex leading to irritative symptoms, such as restlessness, groaning and muttering, jerkings, or rigidity of the limbs. The retinal veins become distended. 3. The stage of anæmia. Further increase of intracranial pressure empties the smaller vessels and produces anæmia with consequent paralytic symptoms. These three stages have been established by direct observation of the brain.

A second basal proposition is that in a case of hæmorrhage these changes are not simultaneously developed all over the brain but are most advanced at the site of the hæmorrhage, so that in a given case the brain lying immediately under the clot may be anæmic and paralysed, around this will be a broader zone which is congested and irritable, while the rest of the brain is normal. Until the congestive stage has reached any given part of the brain no symptoms will be manifested by that part, so that, for example, bulbar symptoms will not appear until the area of circulatory disturbance has reached the bulb. Hence, as is well known, advanced cerebral compression may be present and capable of diagnosis, without the vagus pulse and respiration and the high blood pressure which are so often regarded as the classical symptoms of compression.

The third step in the problem leads us to the significant researches of Harvey Cushing upon the production of these bulbar symptoms. As is well known, he found that when the compression produced such interference with the bulbar circulation as to threaten the vitality of the bulbar centres the vaso-motor centre became active and by constriction in the splanchnic area produced such a rise of blood pressure as sufficed to re-establish the circulation in the bulb. This process he called the vaso-motor reaction and by the demonstration of it he was able to show that the great rises of blood pressure which had long been known to occur in cases of compression are due to a protective mechanism of the utmost importance. This fact is of great significance in treatment, but that aspect of it cannot be entered upon here. The account just given of the appearance of these bulbar symptoms is only the roughest and most general summary of Cushing's experimental results which now demand some further analysis. He found that when the intracranial pressure was raised and simultaneous records kept of it and of the pulse, respiration, and blood pressure, the mode of appearance of the bulbar symptoms might assume four types, which were as follows. 1. With rapid increase of the intracranial pressure signs of great interference with the functioning of the bulbar centres first appeared. The respiration and pulse were markedly inhibited or stopped and the blood pressure fell. After this preliminary failure the vaso-motor centre gradually recovered and the blood pressure rose until it just surpassed the level of the intracranial pressure, the circulation in the bulb being thereby re-established. This form presents interesting analogies with the features of concussion. 2. With gradual increase of intracranial pressure, before the vaso motor reaction appeared vagus manifestations were called forth with slow deep respirations and slow full pulse. Then the blood pressure rose and overtook the intracranial pressure. This was the normal type of occurrence and presents, of course, the features of "classical" compression with coma, slow pulse, stertorous respiration, and high blood pressure. 3. In some animals by a very cautious elevation of the intracranial pressure a rise of blood pressure could be produced which from the first anticipated and kept just ahead of the intracranial pressure. In this way even such disturbance of the bulbar circulation as suffices to call forth vagus stimulation was avoided and a picture of compression with high blood pressure, but without the classical pulse and respiration, was produced. 4. In certain cases which were not susceptible of complete explanation a type of response was produced which is the most interesting of all in relation to the subject of this paper. The blood pressure, instead of rising to just above the level of, and running parallel to, the intracranial pressure developed rhythmic waves (Traube-Hering curves), of which the crests were well above the intracranial pressure and the hollows well below it. This produced a rhythmic blood-supply in the bulb with the result that when the blood pressure was above the intracranial pressure the pulse was strong and full and the respiration of similar type, whereas when the blood pressure was below the intracranial pressure there were the signs of bulbar anæmia—cessation of respiration and weakening of the pulse. Thus was produced, as Cushing himself says, "a sort of Cheyne-Stokes respiration." The curves he publishes show very clearly the occurrence of these periodic phenomena.

Why this rhythmic variation should in some cases replace the ordinary blood pressure reaction is by no means clear and is in need of further investigation. Cushing suggests that it appears as if the blood pressure initially rose too high and produced an over vascularisation of the bulb leading to a corresponding and in some sense compensatory under vascularisation and that the mechanism once started is self-acting. On such a view as this it is difficult to understand the persistence of the phenomenon as seen in Cushing's experiments and clinically—see, for example, Case 1, where the periodic phenomena lasted for four days. In the case of a centre so capable of fine and rapid adjustments as is the vaso-motor centre it would be very difficult to understand that a mere excess of reaction at the onset and the rebound therefrom could become so fixed as to recur without any modification or adjustment whatever for several days. And if the Cheyne-Stokes phenomenon as it occurs in disease is of the same nature as is here suggested for it in head cases a very much greater possibility of persistence would have to be accounted for.

Several interesting lines of speculation suggest themselves but the evidence is not sufficient to justify the following out of them here. It does not seem at the present time that we are justified in going further than saying that the facts of cerebral compression afford confirmation of the primarily vascular nature of the disturbance in Cheyne-Stokes respiration. It is, perhaps, permissible tentatively to suggest that when such disturbance is very slight it may produce respiratory periodicity only when the respiratory centre is, so to say, left to itself as in the hibernating animal or during sleep; that it is even comparatively slight in disease where in some cases, as Pembrey has shown, the respiratory periodicity can be abolished by alterations in the quality of the air breathed; while the vascular disturbance is probably much more profound in cerebral compression.

That the periodic phenomena in their characteristic form are not merely terminal and a mode of vaso-motor failure seems to be shown by the following facts. In Cushing's experiments they were prone, so far as one can judge by a study of his records, to appear quite early in the experiment rather as an alternative method of vaso-motor reaction than at the end of an experiment in which the reaction had been at first normal. Again, in cases of head injury the periodic phenomena appear to come on quite early, as is shown in both the cases related above, though of course it must be remembered that *irregular* periodic phenomena are true terminal symptoms. Moreover, Cushing does not refer to any special feature in the method of producing compression in the cases where the vaso-motor rhythm was called forth and we cannot as yet distinguish clinically any peculiarity of the compressing agent in the cases which display the characteristic Cheyne-Stokes phenomenon. The suggestion which seems finally to emerge—and it is, of course, no more than a mere suggestion—is that *one* method of response by the vaso-motor centre to the call for increased blood pressure is a rhythmic rather than a tonic activity and that this response is perhaps a peculiarity of the individual rather than of the stimulus. Suggestions for further speculative discussion, possibly in the direction of general biology, present themselves, but it seems more desirable to suppress than to indulge them, as it is proposed to attempt some further clinical and experimental investigation.

SUMMARY.

The features of the occurrence of periodic phenomena in cases of cerebral compression upon which it is desired especially to lay stress here are as follows: (1) that the Cheyne-Stokes phenomenon is in such cases no mere terminal symptom and therefore of necessarily slight interest, but one of the most characteristic forms of the vaso-motor reaction and one which may be manifest nearly from the onset of compression; (2) that various modified forms of the phenomenon occur and may cause confusion, especially when the respiratory periodicity is absent; and (3) that periodic movements are no less frequent and characteristic than when the phenomenon occurs in disease and that they may be of diagnostic importance in rendering manifest a paralysis and in being movements which are to be distinguished from those due to focal irritation.

I have to thank the members of the surgical staff of University College Hospital for permission to use the clinical material upon which this paper is founded.

Bibliographical note.—The general literature of the subject without any special reference to traumatic cases is dealt with in Gibson's monograph, "Cheyne-Stokes Respiration," Edinburgh, 1892. Pembrey's work on the modification of respiratory periodicity by changes in the air breathed is referred to in "Recent Advances in Physiology and Bio-chemistry," edited by Leonard Hill, London, 1906. A reference is there made to the original paper by Pembrey and Allen in the *Journal of Physiology*, 1905, but the essential points are all mentioned in the first of these two places. Some account of Cushing's work is to be found in three places. An excellent general exposition was published in the *American Journal of the Medical Sciences*, September, 1902. It is the Mütter lecture for 1901. In the same journal, June, 1903, was published a sequel dealing with the clinical corollaries of the blood pressure reaction and entitled "The Blood Pressure Reaction of Acute Cerebral Compression." A very interesting account with fuller reference to experimental details was published in the *Mitteilungen aus den Grenzgebieten der Medizin und Chirurgie*, Band ix., Hefte 4 und 5, 1902. Finally, there is a full discussion of the bearing of Cushing's researches upon the question of cerebral compression in Kocher's well-known monograph, "Hirnerschütterung, Hirndruck, u.s.w.," in Nothnagel's "Specielle Pathologie und Therapie." In Kocher's book several of Cushing's illustrations and curves are reproduced.

Harley-street, W.

THE ACTION ON BACTERIA OF ELECTRICAL DISCHARGES OF HIGH POTENTIAL AND RAPID FREQUENCY.[1]

BY ALEXANDER G. R. FOULERTON, F.R.C.S. ENG., D.P.H. CAMB.,
LECTURER ON BACTERIOLOGY AND PUBLIC HEALTH TO THE MIDDLESEX HOSPITAL MEDICAL SCHOOL; COUNTY MEDICAL OFFICER OF HEALTH FOR EAST SUSSEX;

AND

ALEXANDER M. KELLAS, PH.D.,
LECTURER ON CHEMISTRY TO THE MIDDLESEX HOSPITAL MEDICAL SCHOOL.

IN the course of an inquiry into the action of "high frequency" electrical discharges as they are employed in medical work the nature of the action of such discharges on bacteria was specially investigated. The majority of the experiments were carried out under the following conditions. The current, obtained from the electric lighting main, was first transformed into a rapidly oscillating current of very high potential by means of an alternator driven by a motor and then into an oscillatory discharge of rapid frequency by means of a condenser and spark-gap. The bacteria were exposed to the action of the discharges whilst suspended in distilled water contained in test tubes. A short length of platinum wire was sealed through the bottom of the test tube and dipped into a layer of mercury at the bottom of the vessel in which the test tube was suspended for cooling purposes. From the mercury in the cooling vessel an "earth wire" passed to a gas supply pipe. The discharges were sprayed on to the surface of the bacterial emulsion from a platinum disc with nine wire points projecting downwards and kept at a distance of about 2·5 centimetres above the fluid. With this arrangement of apparatus the bacteria in the emulsion were exposed (1) to the action of the electrical discharge, and (2) to the action of the electrical current as it subsequently passed through the fluid on its way to earth. Certain modifications of the apparatus were used occasionally but the crucial experiments were carried out with the arrangement described.

Result of spraying the discharges on to the bacterial emulsion through an atmosphere of common air.—When the discharge was sprayed on to the emulsion through an atmosphere of common air it was found that non-sporing bacteria were destroyed after exposures which varied in duration between 7·5 and 15 minutes, while sporing bacteria were more resistant but were also destroyed as a rule within 15 minutes. In each experiment the emulsion was found to be strongly acid at the end of the exposure, the reaction being due to the presence of nitrous and nitric acids in quantities varying between 0·09 and 0·25 per cent., in terms of nitric acid, according to the duration of the exposure and the intensity of the electrical current employed.

The possible factors concerned in the destruction of the bacteria.—It appeared as if four possible factors might be concerned in the causation of the germicidal effect observed in these experiments: (1) the action of the light rays resulting from the discharge; (2) the action of the heat rays resulting from the discharge; (3) the action of germicidal substances formed in the air as a result of the discharge and then taken up in solution by the emulsion; and (4) the direct action of the electrical force itself on the bacteria and apart from concomitant chemical and other action. It was shown by experiment that any germicidal influence of either light or heat rays was negligible under the conditions of the experiments. The chemical substances formed in the air by the action of the discharge included nitrous and nitric compounds, and probably ozone and peroxide of hydrogen. The last two would be rapidly decomposed in the presence of nitrous compounds, and would probably be of importance chiefly in favouring the interaction of nascent nitrous and nitric compounds. Tubes of distilled water were then exposed to the action of the discharge under conditions similar to those prevailing in the former experiments, and after such exposure for 15 minutes the water was found to have taken up considerable quantities of nitrous and nitric acids, and to be capable of destroying bacteria immersed in it for periods of 15 minutes or less. Then solutions of potassium nitrite and nitric acid were made up such as would on admixture yield, after 15 minutes' interaction, an acidity equivalent to that of some of the specimens of distilled water which had been exposed to the discharge. And it was found that such a mixture, with an acidity equivalent to 0·05 per cent. of nitric acid, was capable of destroying all the bacteria which had previously been tested after an immersion of 15 minutes (solutions of nascent nitrous and nitric acids much more dilute than this have an efficient germicidal action). It was concluded, therefore, that under the conditions of the experiments the germicidal action of these substances was sufficient to account for the results observed and without taking into consideration any possible direct effect of the electrical current itself.

---

[1] An abstract of a paper read before the Royal Society on May 3rd, 1906 (communicated by Professor J. Rose Bradford, F.R.S.).

Experiments were next carried out in order to ascertain whether the electrical current and discharge had of themselves, and without concomitant chemical action of the kind referred to, any effect on the bacteria under the time conditions of the experiments. The action of the current alone was tested by passing it directly through the bacterial emulsion without any preliminary discharge above the surface of the fluid by means of a platinum disc immersed just below the surface. It was found that if the germicidal action of heat was excluded an oscillatory current such as had been employed might be passed directly through the bacterial emulsion for as long as 60 minutes without obviously affecting the bacteria in any way.

Attempts were then made to test the possible action of the discharge above the bacterial emulsion, followed by the passage of the current through it by repeating our experiments in atmospheres of various pure gases—hydrogen, nitrogen, carbon dioxide, and carbon monoxide—in the hope of thus avoiding the complicating influence of chemical substances formed in common air as the result of the discharge. In many of these experiments, however, it was found that actively germicidal substances were formed in, or above, the emulsion and could be detected in solution at the end of the exposure. This result appeared to be caused in most instances by the presence of water vapour in the atmosphere in which the discharge occurred. It was found that in an atmosphere of hydrogen peroxide of hydrogen was formed in considerable quantities in some instances, and in some the probable germicidal action of nascent hydrogen had also to be taken into account; peroxide of hydrogen was also present in solution in considerable quantity in experiments in which the discharge was sprayed on to the bacterial emulsion through atmospheres of carbon monoxide and dioxide.

In experiments carried out in an atmosphere of pure nitrogen it was again found that nitrous and nitric compounds were formed and taken up in solution in quantity sufficient to destroy the bacteria present. In experiments of this nature, however, in which chemical changes due to the discharge in the gas above the emulsion were kept at a minimum, no germicidal action was manifested.

Conclusions.—In all the experiments in which a decided germicidal effect was observed it appeared that this was due entirely to the action of substances formed as the result of electrical action on the atmosphere in which the discharge occurred; and it appeared that under the time conditions of the experiments the electrical force employed was not capable of exercising any injurious action on the bacteria tested. And it is probable that when in medical practice cases of lupus and certain other cases in which there is an exposed ulcerated surface are treated by "high-frequency" discharges, the results produced are due entirely to the action on bacteria of nitrous and nitric acids formed in the neighbouring air. And from a therapeutic point of view the use of high frequency discharges in such cases must be looked upon mainly as an efficient method for bringing germicidal substances in a nascent and very active condition into contact with the bacteria present in the lesion exposed to the action of the discharge.

NOTE ON A PECULIAR FORM OF HÆMOPTYSIS WITH PRESENCE OF NUMEROUS SPIROCHÆTÆ IN THE EXPECTORATION.

BY ALDO CASTELLANI, M.D. FLORENCE,
DIRECTOR OF THE CLINIC FOR TROPICAL DISEASES, COLOMBO.

IN Ceylon I have come across two cases of a peculiar hæmorrhagic bronchitis which perhaps it may be of interest to publish. The first case was a man, a Cingalese, aged 44 years, who consulted me in April, 1904, believing himself to be affected with consumption. The *symptoms* were briefly as follows. He had a chronic cough which was generally more severe in the morning; expectoration was more or less abundant and muco-purulent in character; it was non-nummular and not bad smelling. Now and then for periods of two or three days, or even much longer, the expectoration contained blood, the blood being intimately mixed with the muco-pus and varying in amount; sometimes attacks of genuine hæmoptysis occurred, one or two tablespoonfuls of pure blood being expectorated. The patient had suffered from this complaint for two years. All the other members of his family were in good health and there was no history of syphilis. The disease had begun very gradually and without any apparent cause; his general condition had remained fairly good, although a certain degree of anæmia was noticeable; he had not wasted much. He did not complain of night sweats. He had observed rises of temperature, sometimes in the morning and sometimes in the evening.

By examining the mouth and making him spit and cough I satisfied myself that the blood did not come from the gums. The physical examination of the respiratory system, with the exception of a few moist râles at the base of both lungs, was negative. Nothing abnormal was detected in the heart and circulatory system, neither was anything abnormal noted on examination of the other organs. The analysis of the urine was negative. The microscopical investigation of the blood gave the following result: hæmoglobin (Fleish), 60; red blood cells, 4,000,000; and leucocytes, 11,000. An increase (21 per cent.) was noted in the large mononuclears, though there was no history of malaria. *The sputum* was examined three times for Koch's bacillus but always with negative results. The idea occurred to me that it might be a case of endemic hæmoptysis from distoma Ringeri. I made fresh preparations but no ova could be seen; on the other hand, huge numbers of spirochætæ—or what I thought at that time spirilla—were present. I did not then attach much importance to the observation[1] and was inclined to believe the case to be one of tuberculosis, especially as it is well known that the bacillus of Koch may be often absent when the *sputum* is very hæmorrhagic. I inoculated two guinea-pigs with the expectoration collected in sterile Petri dishes; both animals survived; one was killed two months after inoculation and no signs of tuberculosis were present.

I lost sight of the patient for more than a year during which time he constantly took one of the ordinary hypophosphite compounds I had prescribed. In July, 1905, he turned up again. His general condition had improved; he felt much stronger, though the chronic cough with blood-spitting had not sensibly diminished. Physical examination of the chest was again *negative* with the exception of a very few coarse moist râles as on the occasion of the first examination. The sputum was examined almost every day for three weeks but no tubercle bacilli could be found. Several guinea-pigs were also inoculated again with negative results. The expectoration, especially when much blood was present, was teeming with spirochætæ. The saliva and superficial scrapings from the gums were also examined; some spirochætæ were present but always in small numbers.

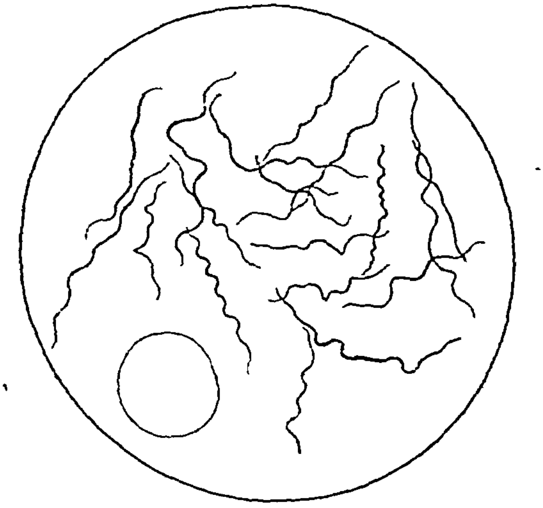
---

[1] Spirilla or spirochætæ have been occasionally seen in bronchial discharge by several authors long ago (Eichhorst, &c.), but the parasites apparently were alw[illegible]ent in small numbers only.

The second case was that of a male Indian. He presented symptoms similar to those of the first case; he had chronic cough with hæmorrhagic expectoration; also occasional attacks of hæmoptysis when a certain quantity of pure blood was spat up. According to the patient there had never been any fever and he had not wasted. He was extremely nervous; in fact, he had become neurasthenic, thinking he was suffering from pulmonary tuberculosis. The physical examination of the chest showed only a few coarse moist râles on coughing in the lower part of both lungs. The sputum never contained tubercle bacilli and the guinea-pigs inoculated remained healthy. Spirochætæ were always present in great numbers, especially when blood and muco-pus were present in large amount. Spirochætæ could be found also in the saliva and scrapings from the gums but only in small numbers.

The spirochætæ were always very numerous and stained well by the Leishman method, generally taking up a bluish tint; they could be stained also with the ordinary aniline dyes, though not so well. They were generally mixed with some bacteria, but sometimes when the sputum was collected in sterile Petri dishes and preparations made at once they were practically the only germs present. Vincent's fusiform bacilli were never observed. These spirochætæ were not all alike. They might be divided morphologically into several groups. 1. Very thick individually, from 15 to 30 microns in length, with irregular waves which varied in number but were never very numerous. The parasites, with the Leishman method, stained deep blue; they were pointed at both ends. 2. Spirochætæ resembling the spirochæta refringens (Schaudinn) with a few graceful waves and pointed extremities. 3. Thin, delicate spirochætæ with numerous small, rather uniform waves and tapering ends. Sometimes one of the extremities was blunt while the other was pointed. 4. Very delicate parasites, though thicker than the spirochæta pallida, with very few waves generally irregular in shape.

All the types I have briefly described may be seen in the illustration. Similar types may be found, according to my experience, also in spirochætæ observed in the mouth; it might be, therefore, that I had to deal with a bronchial or broncho-alveolar localisation of the spirochæta buccalis, which term, there is no doubt, covers many varieties of spirochætæ.



Showing the various forms of spirochætæ observed.

These two cases of hæmorrhagic bronchitis are of an obscure nature; it seems to me that they cannot be considered of a tuberculous origin. The microscopical examination excludes the possibility of a form of endemic hæmoptysis from distomum Ringeri. It might be suggested, perhaps, that possibly the spirochætæ present in such large numbers in the expectoration—sometimes practically without other germs—may have had a part in the etiology of the complaint. It is interesting to note that Plimmer has noticed in guinea-pigs a peculiar form of pseudo-tuberculosis and that in the smears taken from the pseudo-tuberculous lesions he found numerous spirochætæ.

Colombo.

HYPERTROPHY AND DILATATION OF THE HEART IN A CHILD WITHOUT VALVULAR DISEASE OR GENERAL ADHESION OF THE PERICARDIUM.[1]

BY GEORGE CARPENTER, M.D. LOND., M.R.C.P. LOND.,
PHYSICIAN TO THE NORTH EASTERN HOSPITAL FOR CHILDREN;

AND

THEODORE FISHER, M.D. LOND., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN TO THE EAST LONDON HOSPITAL FOR CHILDREN.

OCCASIONALLY cases of death from cardiac disease are seen in the post-mortem room not only in adults but also in children in which the ordinary well-recognised morbid affections of the heart are absent. Although such cases are rare, at least in children, that they do not attract attention more often is no doubt due to the fact that the idea that even slight degrees of mitral regurgitation are sufficient to account for death is deeply sunken in the medical mind. An apical systolic murmur has been heard during life and after death deformity of the mitral cusps is looked for and not perhaps uncommonly found without sufficient reason. One often hears of the expression "thickened edge of mitral" as if the thickened edge were sufficient to account for death. The so-called thickened edge is frequently merely the normal thickening which is situated where interlacing of the fibres of the chordæ tendineæ takes place at their insertion into the mitral cusps. This is made perfectly clear on holding up the large mitral cusp against the light, when the course of the fibres of the chordæ tendineæ between the layers of endocardium forming the cusp can be readily seen. Although, however, we have frequently seen this normal band of thickening considered to be evidence of disease it is needless to say that abnormal thickening may be present in the same situation. When thickening of the mitral valve occurs it affects the fibres of the chordæ tendineæ from their origin at the apices of the musculi papillares to their termination at the mitral ring. As might be expected, this thickening of the fibres of the chordæ tendineæ is most evident where the normal interlacing takes place—that is, at their insertion into the cusps of the mitral valve. Such a band of thickening cannot, however, interfere with the action of the valve. Should regurgitation be present it is generally mainly due to shortening of the chordæ tendineæ, which shortening prevents efficient closure of the cusps. Slight degrees of mitral regurgitation can, however, hardly account for death and certainly cannot explain considerable general dilatation of the heart.

In the case recorded below slight thickening of the mitral cusps of the character which we have indicated was present, but was not sufficient in degree to have interfered in any way with the action of the valve. Mitral regurgitation was present, but in this case it was secondary to dilatation of the orifice, not to shortening of the chordæ tendineæ. The following are brief notes.

A boy, aged eight years, was sent to the North-Eastern Hospital for Children on Sept. 10th, 1905, by Dr. John Spurway of Brondesbury to be admitted under the care of one of us (G. C.). One year previously the boy had suffered from slight "heart trouble," and four months before admission there had been swelling of the elbows, knees, and hands. On admission the cardiac impulse was in the left fifth interspace outside the nipple line. A systolic murmur was present at the apex and a reduplicated second sound over the pulmonary area. On Nov. 6th the liver was noted as being two inches below the costal margin. The cardiac dulness extended also over one inch to the right of the sternum. In addition to the systolic murmur at the apex a to-and-fro sound was heard at the base which Dr. Carpenter considered might be either endocardial or pericardial. The pulse was 140. Some œdema of the legs was present. On the 30th the basic murmur was still present and the pulse was still 140. The œdema of the legs was less. On Dec. 11th it is interesting to note that although the boy was in other ways worse the œdema of the legs had disappeared. He died on Jan. 2nd, 1906.

---

[1] A paper read before the Society for the Study of Disease in Children on Jan. 19th, 1906

At the necropsy the body was found to be wasted. There was no trace of œdema of the legs. The heart was much dilated. It extended from the junction of the cartilages and ribs on the right side to one inch outside the nipple line on the left; it weighed 10½ ounces. The pericardium was perfectly healthy, except that a few small petechiæ were present over the back of the auricles. Nothing could be found to account for the basic murmur. The pulmonary and aortic valves were both competent to the water test and the cusps were free from thickening. The tricuspid orifice was much dilated; it admitted four fingers, but the cusps were healthy. The mitral orifice was also dilated; it admitted three fingers. The chordæ tendineæ were slightly thickened but not shortened. There was no deformity of either the large or the small flap. "Water-marking" of the interior of the left auricle showed that there had been regurgitation through the mitral orifice during life. The cardiac muscle was pale but to the naked eye there was nothing definitely abnormal. The liver extended three inches below the costal margin; on section it presented the characteristic nutmeg appearance. There was nothing noteworthy about any of the other organs except the lungs, which were dotted over with small circular petechiæ. Microscopical examination of the heart muscle showed a few fibres in which fatty degeneration was considerable and many others in which small granules were scattered throughout the fibres, but the amount of fatty degeneration was not greater than is frequently seen in death from almost any cause. There was little or no increase of interstitial tissue. The microscopical examination threw no light upon the nature of the hypertrophy and dilatation.

As has already been mentioned, the main morbid condition present was dilatation, associated with hypertrophy of the heart, and the question of the causation of this dilatation and hypertrophy presents itself for consideration, as it does in all cases in which valvular disease and general adhesion of the pericardium are absent. In adults there are several causes of such a morbid condition of the heart, but in children possibly almost the only cause is rheumatism. Symptoms of cardiac weakness appear to have occurred in this boy before swelling of the joints was noticed, yet the fact that rheumatism definitely had at one time been present strongly suggests that there had been also an earlier attack which had fallen mainly upon the heart.

The idea, however, that rheumatism, apart from valvular disease and general adhesion of the pericardium, can cause enlargement of the heart may appear fanciful. Let us consider for a moment, however, the enlargement which occurs in association with pericarditis due to rheumatism. In such cases not only dilatation but hypertrophy of the heart may be remarkably rapid. We have seen pericarditis develop in a girl, aged 11 years, while under treatment for chorea and cause death within a fortnight, at the end of which time the heart was more than double the normal weight for a child of that age, and such an event, which was noticed many years ago by Dr. J. F. Goodhart, is by no means uncommon. No other disease but rheumatism produces such a rapid increase in weight of the heart. It may be said that such rapid increase of weight must be due to imbibition of fluid. That may be so, but the heart does not return to a more normal size when the inflammation of the pericardium has subsided. On the contrary, the hypertrophy is generally progressive and the enlargement may become so great that even a child 12 years of age may possess a heart weighing 30 ounces. Barnard, Sequeira, and others have given a simple explanation for the dilatation of the heart in pericarditis. They consider that the pericarditis causes softening of the fibrous pericardium, which yields and allows dilatation of the heart. Hypertrophy follows this dilatation. If, however, softening of the fibrous pericardium were the explanation of dilatation of the heart associated with pericarditis, the dilatation should occur not only in rheumatic pericarditis but in other forms of pericarditis. But in forms of pericarditis equally, if not more virulent, such as the suppurative pericarditis of pneumonia, or of pyæmia, little or no dilatation of the heart takes place. This absence of dilatation in suppurative pericarditis one of us (T. F.) has long pointed out in the post-mortem room and mentioned it in reply to Dr. J. H. Sequeira at a meeting of the Society for the Study of Disease in Children in October, 1900. It is interesting to note, however, that Dr. G. F. Still has since commented upon the same fact.[2]

Since the difference in degree of the dilatation of the heart which occurs in association with rheumatic pericarditis and in suppurative pericarditis is very great, it seems clear that the dilatation rests upon no such simple causation as yielding of the fibrous pericardium. It depends, we believe, upon something more subtle, upon a poisoning of the heart which affects it chiefly in this way during the growing period of life. After the age of 20 years rheumatic pericarditis causes little or no dilatation of the heart. Allowing, however, that the enlargement of the heart is due to rheumatic poisoning, it is nevertheless true that such enlargement is rarely seen to follow rheumatism unless pericarditis has been present. But this is not surprising. Pericarditis is, no doubt, an evidence of the most intense form of rheumatic infection of the heart, and to get infection which attacks the cardiac muscle while the pericardium escapes can hardly be expected to be common. It must also be remembered that some general cardiac hypertrophy is not uncommon in mitral stenosis. To explain hypertrophy of the left ventricle on mechanical grounds in mitral stenosis is not easy. It seems far more reasonable to allow that the hypertrophy is the result of some interference with the nutrition of the cardiac wall by the rheumatic poison. But however that may be, cases are undoubtedly to be seen from time to time of enlargement of the heart without valvular disease and without general adhesion of the pericardium in children who have suffered from rheumatism, and it is reasonable, in the absence of evidence of other causation, to attribute that enlargement to the rheumatism.

OSSIFICATION OF THE FONTANELLES AND CLOSURE OF SUTURES AT BIRTH—A CAUSE OF DIFFICULT DELIVERY.

By T. LEAHY-LYNCH, L.R.C.P., L.R C.S. & L.M. EDIN., L.F.P.S. GLASG.

A PRIMIPARA, aged 33 years, with vertex presentation in the first position, who was in labour for the usual number of hours, completed the first stage normally. I ruptured the membranes and left the patient a reasonable time to complete the second stage, but she exhibited failing strength and asked for my help. She was very nervous, so I determined to send for my partner, Mr. R. J. Mackay, to give an anæsthetic and to deliver her with forceps. She was got well under anæsthesia and the forceps was applied, but the handles were separated when the instrument was locked. Delivery was much more difficult and took longer than had been anticipated. For this I endeavoured to find a cause. The third stage over, I examined the baby's head; there were *no moulding*, no overlapping of the parietals over the frontal and occipital bones, and no overlapping of the parietal bones themselves; there was no trace of a posterior fontanelle or of those at the anterior inferior angles of the parietals; there was a mere depression over the anterior fontanelle or bregma; the sagittal suture was closed as well as the frontal, the coronal, and the lambdoid. In fact, ossification was complete in the fontanelles and sutures. The child was a healthy male, 21 inches in length, and weighing eight and a half pounds. No hydrocephalus was present. The blade of the forceps marked the infant slightly over the left mastoid region. The mother displayed symptoms of puerperal insanity on the third day. She rambled, wanted to get out of bed, looked strange, buried her head in the pillow, took little notice of her surroundings, would scarcely answer when spoken to, and would not take nourishment. She had diarrhœa, anorexia, and the breasts were empty. The temperature and lochia were normal. She was kept quiet and the baby was taken away; large doses of bromide of potassium and aromatic spirit of ammonia were given, after which several hours' rest were obtained and the symptoms quickly passed off. The breasts filled and the patient became quite well.

---

[2] Brit. Med. Jour., vol. ii., 1901, p. 606.

My object in recording these facts is to show that the shock of delivery must have been very severe for the patient. The text-books give little information on this point. Herman's "Difficult Labour" does not mention it. Galabin (p. 93) mentions that "the male head is more firmly ossified at birth than the female skull, is half an inch more in circumference; hence arises greater protraction of labour in the case of males, more frequent necessity for artificial aid, and greater mortality both to mothers and children." Cazeaux and Tarnier's "Theory and Practice of Obstetrics," vol. iii., p. 839, states: "To this cause, dystocia, our colleague and friend, Dr. Joulin, Adjunct Professor of the Faculty of Medicine at Paris, devoted a long chapter of his thesis for the Concours. According to him the Germans admit that trouble may be due to the size of the head alone, besides which they also call attention to a peculiarity of the ossification little known in France, which adds to the difficulty of the situation—viz., the development of Wormian bones in the fontanelles causing their solidification." "It is very hard to determine what ought to be done in cases of this kind; it is almost impossible to become aware of the size of the child whilst it is still within the womb, so that the practitioner who finds the progress of the case arrested in an apparently well-formed pelvis will very probably decide upon active interference before the true cause of the delay is detected and apply the forceps or cephalotribe according to the amount of difficulty which the size of the head shall present to its extraction" (Joulin). "The fontanelles at inferior angles of parietal bones close soon after birth. The posterior fontanelle closes in a few months, the anterior remaining open until the first or second year. Sometimes this fontanelle remains open beyond two years, and occasionally persists throughout life" (Gray).

I shall be glad to know if this condition is often met with and the best means of its diagnosis, as the guides to the fontanelles—viz., the sutures—were in this case closed.

Finsbury Park road, N.

A NOTE ON THE INFLUENCE OF ANTITOXIC SERUM ON THE TUBERCULO-OPSONIC INDEX.

BY T. R. BRADSHAW, M.D. DUB., F.R.C.P. LOND.,
PHYSICIAN TO THE LIVERPOOL ROYAL INFIRMARY; EXAMINER IN MEDICINE IN THE UNIVERSITY OF LONDON, ETC.

WHILE preparing a paper on the opsonic index, a paper which was read jointly with Dr. E. E. Glynn on May 3rd before the Liverpool Medical Institution and which will be published in full in the summer number of the *Liverpool Medico-Chirurgical Journal*, I made a number of estimations for the purpose of ascertaining for myself the fact generally accepted that the tuberculo-opsonic index is practically the same in all non-tuberculous individuals. On one particular day I determined the index of seven persons, free from all suspicion of tubercle, four medical men, two nurses, and a young man, D., in my ward who was recovering from an attack of neuritis, the result of diphtheria, for which he had been treated with antitoxic serum about three months before. The index of the first six worked out well within the accepted normal limits of variation but to my surprise the index of the patient was only half the average of the others. The following are the exact figures: Dr. B., 1·14; Mr. S., 1·05; Mr. C., 0·97; Mr. H., 0·96; Nurse A., 0·95; and Nurse B., 0·92; average 1·00. Patient D., 0·47. The other counts agreed so closely that I felt confident I had made no mistake in carrying out the estimations and I was inclined to suspect that the patient in question had some local tuberculous infection which I had not been able to discover. My late house physician, Mr. C. H. Smith, however, suggested that the low index might be a consequence of the inoculation with antidiphtheritic serum three months before. One of his colleagues, Mr. W. Yorke, had noticed a marked depression of the tuberculo-opsonic index following the administration of a prophylactic dose of antitetanic serum given to a healthy man who had reason to fear he had exposed himself to the risk of inoculation with tetanus. To test the correctness of this explanation I took the tuberculo-opsonic index of eight other individuals who had been treated with antidiphtheritic serum. In three of the cases a second estimation was made after an interval. The following table shows the opsonic index in each case and the time which had elapsed between administration of the antidiphtheritic serum and the estimation of the index.

No. of case.	Interval since the antidiphtheritic serum was administered.	Index.
1	2 days	1·30
	5 ,,	0·64
2	12 ,,	1·02
	25 ,,	0·35
3	27 ,,	0·89
	41 ,,	0·72
4	25 ,,	0·64
5	26 ,,	0·72
6	26 ,,	0·62
7	27 ,,	0·77
8	28 ,,	0·69
9	3 months.	0·47
Average		0·73

It thus appears that in all the nine cases examined the tuberculo-opsonic index was found below the normal at some period subsequent to inoculation with antidiphtheritic serum. The depression seems to have increased for some time and in Case 9 to have persisted for months. Cases 1 and 2 suggest that the immediate effect of the inoculation is to raise the tuberculo-opsonic index but the data are too scanty to enable us to generalise on this point. It is obvious that it must be of the utmost importance to bear in mind the possibility of some such cause as was present in the foregoing cases before giving an opinion on the significance of a low opsonic index. As to the nature of the influence of the antitoxic sera, antitetanic as well as antidiphtheritic, on the opsonic index it is premature to offer any positive opinion. It is not unreasonable, however, to assume that it is due to some property inherent in the blood of the horse and has nothing to do with the specific antitoxins.

I have to thank my present house physician, Mr. G. L. Cox, for his assistance in carrying out the estimations.

Liverpool

EXTENSIVE RUPTURE OF THE LIVER WITHOUT EXTERNAL INJURY.

BY F. SEYMOUR LLOYD, M.D. LOND.

AT 9.30 P.M. on May 1st I was called to see a brewer's drayman who had just been brought in by his companions and found him to be dead. As no one witnessed the accident it is impossible to say exactly how it occurred, but it seems probable that as the man was in the act of mounting to the box his horses started off suddenly and trying to pass a dray standing just in front of them squeezed his body between the projecting hoods of the two vans. The first intimation that anything was wrong was received by the driver of the first van who, surprised to find the second van starting before his own, looked down and saw it passing with the deceased hanging by the hands to the stays just below the hood. Immediately the dray forged in front, however, he let go his hold, regained his feet, and darted on to the sidewalk where he leaned against a parapet with his head on his left arm and his right hand compressing his abdomen. He appeared to be in great pain and made as if to vomit, but did not do so; after a little while he tried to pull himself together and said, "All right, mate, I'll drive them home." These were the only words he was heard to utter. He then, unaided, mounted to his box and drove the horses a distance of about 400 yards when the draymen following with other vans saw his head fall over to the right. They ran and stopped the horses and carefully lifted him down from the box and laid him comfortably inside the dray on a bed of straw. Here he lay groaning and rolling uneasily about. He was last heard to groan when about two and a half miles from Luton, where he arrived half an hour later, when I was called to him. The head and hands were pale and icy cold, the trunk being just warm to the touch. The body and limbs were flaccid throughout. The features were pale but composed and the expression was peaceful. Urine and fæces had been passed into the clothing. Careful examination of the body failed to reveal any bruise, discolouration, or other evidence of injury other than two small scratches, one on the right malar process and the other on the tip of the left ear. There was no sign of bleeding from the nose or mouth, though there were small recent bloodstains on his apron; these possibly came from the scratch on his cheek. The abdomen was much distended and highly tympanitic except for a space of two and a half inches in the flanks, more markedly in the right flank. The man was a magnificent specimen of humanity and measured six feet five inches as he lay on the mortuary table. He had been known for his strength and was extremely popular with his comrades.

In accordance with instructions from the coroner I performed a necropsy on the afternoon of May 3rd, 42 hours after death. The body was rigid throughout and post-mortem staining was marked especially in the neck and shoulders. On opening the parietes the abdominal cavity was found to contain a large quantity of thin dark blood; there were also numerous flocculent clots of small size entangled in the meshes of the omentum and between the coils of the intestines, and in the right hypochondrium were larger clots varying in size from that of a marble to that of a fowl's egg. The liver was retracted well under the ribs and only a small portion of the left lobe was visible at the epigastric angle. It was carefully removed and presented the following appearance. The liver was large in conformity with the splendid development of the subject; it appeared pale, but was perfectly healthy in substance. Through the thickest portion of the right lobe was a tremendous fissure, running backwards through both capsule and glandular substance from the anterior edge to the posterior surface, and being so complete that the liver was all but divided by it into two portions, only a narrow bridge of liver tissue about an inch thick connecting them. The fissure was straight and was eight and a half inches long, the surfaces exposed by it being rough and granular looking. The greatest breadth of the torn surface was roughly four inches, tapering thence to a point towards the anterior edge. About the centre of this fissure was another contused tear three inches long running perpendicularly to it outwards to the right; this, however, only penetrated the liver substance for a depth less than half an inch; one or two smaller tears radiated from the point of junction of the major tears in a stellate manner. The gall-bladder and the rest of the liver were normal, as were all the other abdominal viscera. The intestines were collapsed and the stomach was empty. There was no fracture or injury to any of the ribs or the spine. The lungs were normal but were very retracted and pale. The heart was normal. Death evidently resulted from shock and internal hæmorrhage. The deceased had been a most temperate man.

Remarks.—The case furnished several points of interest. 1. The remarkable length and completeness of the rupture. 2. The fact that there was no concomitant injury to the bones or soft parts. This may be accounted for in three ways: (*a*) The thickness of the man's clothing, apron, coat, &c., the evenings being chilly. (*b*) The force was not an instantaneous force delivered by an instrument of small surface area but was presumably a rolling force of large area represented by the surfaces of the board hoods The effect of one dray moving would be to give a "spin" to the body comparable to the action of a mangle. It would thus be squeezed, the pressure increasing until the moment of closest approach of the drays, and lessening as they drew apart. The capsule of the liver stood this severe strain as long as it could and then, the force still continuing to act, burst open. (*c*) His muscular development. In this young (he was 28 years of age) muscular man the elasticity of the ribs responded well to the strain. 3. That in a case of such extreme injury the sufferer should be able to walk and to mount his box, no easy feat as I proved for myself. Also that he should be able to drive for 400 yards. 4. The very rapid cooling of the body owing to the abstraction of blood from the extremities. Though he could not have been dead for more than half an hour at the most the trunk was only just warm.

Luton.

> Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.*, lib. iv., Proœmium.

LONDON HOSPITAL.

A CASE OF LIGATURE OF THE COMMON FEMORAL ARTERY AND VEIN; GANGRENE; AMPUTATION; RECOVERY.

(Under the care of Mr. J. HUTCHINSON, jun.)

FOR the notes of the case we are indebted to Dr. H. F. Horne, late house surgeon to the hospital.

A butcher, aged 22 years, was admitted into Cotes ward of the London Hospital on Sept. 1st, 1905, suffering from severe hæmorrhage and collapse. The history of the case was that while engaged in his occupation and dismembering a carcass the double-edged knife he was using slipped and entered the right thigh. On admission he was much collapsed, almost pulseless, the lips were much blanched, and his clothing was saturated with blood. A pad had been applied over the wound and tightly bandaged. No pulsation could be felt in the posterior tibial artery. Ether was administered immediately on admission and a transverse wound was found in the right thigh one inch in length, situated one inch below Poupart's ligament, through which opening blood flowed freely on removing the pad. By digital pressure the iliac artery was compressed against the brim of the pelvis and a longitudinal incision five inches in length was made in the line of the artery and exposed the femoral vessels. The vein and artery were both partially severed and had retracted, a small piece of the vessel wall connecting the upper and lower portions in each case. The upper portions which had retracted under Poupart's ligament Dr. Horne pulled down with Spencer Wells's artery forceps and applied silk ligatures to each by means of an aneurysm needle, the anterior crural nerve being held out of the way. The lower segments of the vessels were similarly dealt with. The wound was partially closed with silkworm-gut sutures and plugged with sterilised gauze. After the vessels had been secured four pints of normal saline solution were injected into the basilic vein of the left arm and the patient was given half a grain of morphine hypodermically on recovering from the anæsthetic, which caused considerable improvement in the pulse. The patient was kept fully under the influence of morphine for the succeeding 48 hours. The leg and foot were thoroughly cleaned and every precaution was taken to keep up the circulation of the limb. With division of both artery and vein it was scarcely to be expected that gangrene could be averted.

The wound was dressed on Sept. 3rd and was found to be quite healthy. Discolouration of the skin had appeared on the foot and extended up the leg to within three inches below the knee. During the following 12 days the wound was continually redressed and gradually closed. The toes and foot gradually became mummified, the gangrene apparently not spreading higher up the leg, and the temperature kept normal. On the 16th the gangrenous area had extended to the upper end of the tibia; the leg was swollen and green, smelling offensively, and one or two small blisters had appeared on it. The pulse was slightly quickened and the temperature had risen to 102·5° F. By the following day the area of gangrene had reached the upper border of the patella. Dr. Horne therefore amputated at the junction of the upper and middle thirds of the thigh by a longitudinal external and circular incision round the thigh. The femoral vein was seen much shrunken and contained a hard clot. The lower segment of the femoral artery was found to be of the size of a goose quill and feebly bleeding; the surrounding tissues seemed healthy. Three pints of normal saline solution were injected intravenously during the operation as the patient became collapsed. The wound was closed with silkworm gut sutures, a large spiral rubber drainage-tube being left in.

On the morning of Sept. 18th a dark patch of discolouration appeared at the inner angle of the wound, the remainder of the stump being quite warm. The temperature was 100° and the pulse was 102 and strong. On the following day a dark green patch of gangrene appeared at the inner side of the stump. On taking out the sutures the end of the stump was found to be in a sloughing foul-smelling condition and was accordingly syringed out at hourly intervals with peroxide of hydrogen solution, packed with iodoform and boric powder in equal parts, and enveloped in hot lysol fomentations. The patient's temperature was 103·5°. On the 21st the temperature was 100·5°; the gangrene had not spread and small pieces of the slough were beginning to separate. On the 23rd the wound appeared more healthy, some slight bleeding occurring from both flaps. The temperature was 99° and the pulse was 100. By the 25th some pus exuded from the wound on pressure and the under surfaces of the flaps began to show signs of granulation. The dead tissues were completely removed on the 28th; the stump appeared to be quite healthy and granulation tissue was appearing. The cut end of the femur projected from the muscles but no pus exuded from the bone. The iodoform and boric powder were now discontinued, the wound being plugged with wool soaked in hydrogen peroxide. The fomentations were still continued. The incision made for ligating the vessels had completely healed by Oct. 3rd and the stump was gradually healing. On the 23rd the flaps were trimmed and the projecting piece of bone was removed. The wound was sewn up and a drainage-tube was left in, which was removed on Nov. 7th. There was no further rise of temperature and the patient left the hospital early in December.

Remarks by Dr. HORNE.—As an uncommon case of emergency surgery I have thought the above sufficiently interesting to be placed on record. The opportunity is rarely afforded of surgical interference in wounds involving the main vessels, for before assistance can be obtained so severe an injury usually proves rapidly fatal. On referring to the literature on the subject I find that Mr. A. Pearce Gould in THE LANCET of Feb. 5th, 1887, p. 258, publishes a case of a wound of the common femoral vein and secondary hæmorrhage from the common femoral artery followed by septicæmia and death. In this article he gives a table of nine cases of wounds of the femoral artery and vein collected from various sources. Of these two died in a few minutes after the accident, one case recovered, and six died subsequently to the operation, two of whom developed gangrene. At a meeting of the Clinical Society of London in 895 Mr. C. S. Wallace showed a case in which the femoral essels were tied for secondary hæmorrhages, the patient making a perfect recovery.[1]

I wish here to acknowledge the kindness of Mr. Jonathan Hutchinson, jun., in allowing me to perform the amputaion when it became necessary and to publish this case.

Note by Mr. J. HUTCHINSON, JUN.—The extreme gravity of wounds of the common femoral vessels is well illustrated by the case now recorded by Dr. Horne and by those alluded to in Mr. Pearce Gould's table. To these I can add one more—a youth who died very soon after severance of the femoral artery by a chisel. Thus, out of a total of 11 cases only two recovered, including the man who owed his life to Dr. Horne's prompt interference. With regard to this case the right course after securing the divided vessels was undoubtedly followed—that of waiting to see how far the gangrene would extend. Up to the end of a fortnight, when the patient had quite recovered from the primary shock and loss of blood, we hoped that an amputation just above the knee-joint would suffice; but then the gangrenous process rapidly spread, changing from the dry to the more dangerous moist form, and the symptoms of septic absorption forbade any further delay. The sloughing which followed high amputation was unexpected and most alarming; indeed, with such a large septic surface it looked as though the patient could hardly recover. The result ultimately attained was very satisfactory.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.

A CASE OF CONTRACTURE OF THE HAND TREATED BY RESECTION OF PORTIONS OF THE BONES OF THE FOREARM.

(Under the care of Mr. CHARLES A. MORTON.)

A BOY, aged 10 years, was admitted to the Bristol Hospital for Sick Children on March 4th, 1904, with the history that eight months before he had fractured the bones of the left forearm. Splints had been at once applied and were kept on for a month. The patient was seen by the medical attendant the day after the splints were applied and they were loosened by him a week later. The mother said that when the splints were taken off the forearm was "quite rotten" on both sides and that later the skin came off and the hand became gradually bent. It was clear from the history that he could move his fingers and that there was no contraction when the splints were removed, but how much he could move his fingers and whether contraction had been prevented up to that time by the splint reaching to the ends of the fingers there was no means of ascertaining. The contraction of the hand was increasing at the time he went into hospital. There were deep, dense scars on both aspects of the forearm but especially the flexor, as if the muscles as well as the skin had sloughed. The hand was fixed in the flexed position, quite at a right angle with the forearm, and the only movements possible were those of the index and middle fingers and these were very slight. There was no anæsthesia. When the boy attempted to move the fingers the muscles of the forearm were seen to contract down to the level of the scar tissue but not beyond. As the contraction was so great and the structures on the flexor aspect of the forearm were so matted together and to a large extent even destroyed, it seemed clear that only shortening of the bones would allow the hand to be straightened. Mr. Morton did not expect to get much use in the hand. The boy had been taken to another hospital before going to the Children's Hospital and the mother had then been told that the only thing to do was to amputate the hand and therefore she was content to have anything done which would be likely to give her child a hand as useful as, or a little more useful than, an artificial one.

On March 23rd Mr. Morton resected an inch of both the radius and ulna so as to permit the wrist to be straightened, and wired the ends of the bones together. The wound united by primary union and the bony union was quite satisfactory. The wires were later removed. A few weeks after the operation he could slightly move all the fingers but not the thumb. Two months later, after frequent massage and passive movements he could move the fingers a little better and had a very feeble grip. A leather splint was applied to prevent re-contraction of the wrist and he was sent to his home in Wales at the end of June. Mr. Morton saw him again in May, 1905, when he found that the continued use of the leather splint had prevented any re-contraction of the wrist but that the use of the hand had not returned to any great extent. It was, however, better than an artificial hand. The patient could pick up light things between the thumb and the ring finger, and could flex all the fingers and the thumb at the metacarpo-phalangeal joints. The ring finger was considerably flexed and the middle finger was slightly flexed.

Remarks by Mr. MORTON.—As few cases of contracture of the hand treated by resection of the bones of the forearm have been published, the report of the foregoing case may be of value. As I did not see the boy until eight months after the fracture I cannot say whether it was a case of true ischæmic paralysis or whether the loss of power and contraction was wholly due to the destruction of the muscles by sloughing and the contraction of the scar tissue. Sloughing from the pressure of the splints is very common in Volkmann's contracture and it is quite possible that the two conditions were associated in this case.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

General Meeting.—Operation for the Radical Cure of Femoral Hernia.—Appendicitic Abscess associated with Multiple Liver Abscesses.

A GENERAL meeting of this society was held on May 14th, Sir LAUDER BRUNTON, the President, being in the chair.

The following was the result of the election of officers and council for the ensuing year:—President: Mr. C. A. Ballance. Vice-Presidents: Dr. W. Pasteur, Mr. C. W. Mansell Moullin, Mr. John Tweedy, and Sir Edgcombe Venning. Treasurer: Mr. D. H. Goodsall. Librarian: Dr. A. F. Voelcker. Honorary secretaries: Mr. C. S. Wallace and Dr. F. J. Poynton. Honorary Secretary for Foreign Correspondence: Mr. H. J. Waring. Council: Mr. R. C. Bailey, Sir Hugh Beevor, Bart., Mr. C. Carter Braine, Dr. J. F. H. Broadbent, Sir Lauder Brunton, Dr. H. A. Caley, Dr. Edmund Cautley, Dr. G. H. A. Comyns Berkeley, Dr. J. H. Drysdale, Lieutenant-Colonel R. W. Ford, R.A.M.C., Dr. A. E. Garrod, Mr. Francis Jaffrey, Mr. T. H. Kellock, Mr. John Langton, Dr. C. A. S. Leggatt, Dr. Percy J. F. Lush, Dr. F. S. Palmer, Dr. J. S. Risien Russell, Mr. H. P. Symonds, and Mr. W. H. C. Staveley.

The annual reports of the council, honorary librarian, and chairman of the house and finance committee were presented and adopted.

An ordinary meeting was then held and

Mr. W. H. BATTLE read a paper on a Method of Operation for the Radical Cure of Femoral Hernia. He commenced by saying that it was more difficult to deal with large femoral herniæ than with those of similar size in the inguinal region. There was also a greater tendency for the ring to enlarge. The operation he was about to advocate was first performed by him in 1899.[1] After thoroughly cleansing the parts a vertical incision was made over the sac and the contents were dealt with in the usual way. The object of the operation was to form two flaps, an inner and an outer, and to slide the inner behind the outer, securing it over the upper opening of the femoral canal. These flaps were then sutured in position and thus a shutter of living tissue of great strength was placed below the ligatured neck and across the upper end of the femoral canal. Usually no drainage was required. In only one case was the wearing of a truss necessary afterwards. Including the cases mentioned in his paper in THE LANCET in February, 1901, Mr. Battle had operated in this way on 64 cases of femoral hernia for its radical cure. One case was under 20 years of age, 14 cases were between 20 and 30, 23 cases were between 30 and 40, two were between 50 and 60, and two were over 70. The duration of the hernia had varied from a few days to 20 or 30 years. 30 cases were reducible, 30 were irreducible, and four were strangulated. In only four cases did any suppuration ensue. There were no deaths. Only one patient had returned with a recurrence of the hernia, but it was only right to mention that some had been only recently operated on. A somewhat similar operation had been described independently by Mr. R. H. Parry[2] in October, 1901, only he advocated the suturing of the conjoined tendon of Poupart's ligament to Cooper's ligament. In conclusion, Mr. Battle claimed the following advantages for the operation which he had described: (1) the suppression of every trace of the peritoneal infundibulum by the application of a ligature to the highest possible level of the hernial sac, (2) the annihilation of the femoral ring; and (3) the replacement of the septum crurale by a strong musculo-aponeurotic screen. Cases were narrated and illustrated by lantern slides.—Mr. CUTHBERT S. WALLACE remarked on the difficulties of closing the internal ring in such cases and the rigidity of the parts around and the proximity of the great vessels. He thought the operation was a good one and he believed the main cause of its success lay in the application of the three sutures along the line of the inguinal canal which were freed from tension by the second flap. The results of this operation seemed to be very good.

One of the Hon. Secretaries read (for Mr. H. J. CURTIS of Bulawayo) a paper entitled, "A Successful Case of Appendicitic Abscess associated with Multiple Liver Abscesses." The patient was a man, aged 35 years, who had suffered from malaria, dysentery, and syphilis in the preceding years and was admitted to the Bulawayo Memorial Hospital on Oct. 13th, 1904, with a history of one month's abdominal pain. The temperature was 99·8° F., the pulse was 128, and the respirations were 52. There was tenderness at McBurney's point but no swelling. On Oct. 18th a tender swelling appeared in front of the right kidney. On the 19th the abdomen was opened and an inflamed, red, and kinked appendix was removed from behind the cæcum. While this was being done an abscess over the kidney was opened and a large tube was inserted. The abscess was not in contact with the appendix and reached up to the costal margin. On the 31st a large abscess in connexion with the liver was opened through the right tenth intercostal space. The pus was of the "anchovy paste" variety. On Dec. 11th the same kind of pus was noticed in the sputum and on the 16th there was severe hæmoptysis. On the 17th the liver abscess was further explored and a larger tube was introduced. Iodide of potassium in increasing doses was now given and steady improvement was maintained until the patient was discharged on April 1st, 1905. Mr. Curtis then reviewed the details of the case and pointed out as remarkable the absence of high fever when the patient first came under observation. It was open to doubt if the abscess was dependent on the appendix trouble or on the dysentery from which the patient had previously suffered. Amœbæ were found in the pus and probably the appendicitis was an accidental complication of tropical abscess of the liver. The prognosis of liver abscess complicating appendicitis and the frequency of this association were finally discussed.—The PRESIDENT, commenting on the use of iodide of potassium, drew attention to the extremely large doses which could be tolerated with advantage in such cases.—Mr. BATTLE discussed the association of the two lesions and the likelihood of their being accidentally or causally connected. Possibly the hepatic lesion was tropical abscess and the appendicitis simply concurrent.

CLINICAL SOCIETY OF LONDON.

Cystic Tumour of the Spermatic Cord.—Carcinoma of the Thyroid Gland.—Perforated Gastric Ulcer treated by Evisceration and Irrigation.—Complete Removal of a Multilocular Cyst of the Pancreas.

A MEETING of this society was held on May 11th, Mr. H. H. CLUTTON, the President, being in the chair.

Mr. CUTHBERT S. WALLACE described a case of Cystic Tumour of the Spermatic Cord. A man, aged 41 years, was admitted to St. Thomas's Hospital in 1904 with what appeared to be an irreducible inguinal hernia and gave a history of abdominal pain and vomiting. However, at the operation a tumour was revealed which consisted of two main cysts with numerous smaller ones, the whole mass lying in the cord beneath the cremaster muscle. At the internal ring the tumour disappeared within the abdomen and could be felt to form a considerable mass in the pelvis. The inguinal portion of the tumour was excised. The operation was followed by recovery with atrophy of the testis from damage to the spermatic artery. Mr. Wallace regarded this case as being of the same type as those described by the older writers under the title "diffuse hydrocele of the cord." Percival Pott in 1773 was the first to describe the condition and he was of the opinion that it was of the nature of an œdema and this view was the one still put forward in English books which make mention of the subject. Mr. Wallace believed that this explanation could not be accepted. The so-called cystic adenomata of the testis and kidney were supposed to arise in remains of the Wolffian body and in their construction were very similar to the tumour under discussion. When the original relation of the testis and kidney was borne in mind it seemed possible that the fœtal remains found in these two organs might also be found in the spermatic cord. It appeared, therefore, not improbable that "multilocular cystic tumour of the spermatic cord" had a similar origin in remains of the Wolffian body.—Mr. E. PERCY PATON referred to a female patient, 30 years of age, whom he had seen for irreducible hernia. A small cystic tumour was found in the inguinal canal similar in character to that described by Mr. Wallace.—Mr. T. H.

[1] THE LANCET, Feb. 2nd, 1901, p. 302.
[2] Brit. Med. Jour., Oct. 19th, 1901.

KELLOCK thought that such tumours resembled rather the tumours known as hydrocele in the neck, and asked if the fluid had been examined. Another possibility which had occurred to him was whether the tumour might have been an abnormally placed and cystic kidney.—The PRESIDENT quoted a case like that narrated by Mr. Wallace and thought the subject should be referred to more in current text-books. The condition was certainly not a diffuse hydrocele of the cord as at present described in text-books.

Mr. A. C. HUDSON read a paper, illustrated by the epidiascope, on Carcinoma of the Thyroid Gland. A description was given of eight cases of tumour of the thyroid exhibiting the characters of malignant invasion and of six other cases in which, although the ordinary clinical features of malignant disease were absent, the tumours showed the histological structure of carcinoma. Two tumours discovered at necropsies were also described. Reference was then made to the mode of origin of the capsule of a simple adenomatous thyroid tumour and its possible significance in the study of the behaviour of carcinomata. The cases described pointed to malignant disease of the thyroid being somewhat commoner and at the same time more amenable to surgical treatment than was perhaps generally believed. These cases also emphasised the difficulty likely to be experienced in correctly estimating the degree of malignancy of epithelial thyroid tumours solely from the type and arrangement of the epithelial cells and other histological features. There were, moreover, cases of undoubted carcinoma in which metastasis did not occur and the histological structure of these tumours presented various transitional forms.—The PRESIDENT referred to several cases of carcinoma of the thyroid which he had operated upon. The first of these he met with in 1886 and the next in 1903; both of these patients were still living. In another case met with in 1905 the diagnosis presented some difficulty; the tumour was partially removed and although the growth had perforated the trachea the patient did well. Speaking of the diagnosis, the President said that malignant growths, though they might be very small, were more firmly adherent to the trachea than adenoma or any other tumour and were very often encapsulated. The clinical history of such cases was very different from carcinoma in other places, as the tumour was so much slower in its progress.—Dr. C. W. WIRGMAN had seen several cases in which the bones had become secondarily involved, although some of these cases had resembled adenomata in their clinical and microscopical characters.—Mr. W. G. SPENCER remarked that thyroid carcinoma appeared to have such special features of its own that it would perhaps be better to describe cases like those narrated by Mr. Hudson by a special designation, such, for instance, as adeno-carcinoma.

Mr. E. W. ROUGHTON communicated a case of Perforated Gastric Ulcer treated by evisceration and irrigation. The patient was a woman, aged 26 years, who had had indigestion for three weeks followed by symptoms of perforation. The abdomen was opened five and a half hours after the onset of the symptoms and the perforation was closed by sutures. As the stomach contents had escaped freely, soiling all parts of the peritoneum, the abdominal incision was prolonged, the small intestines were turned out, and the abdominal cavity was thoroughly irrigated. The irrigation was commenced in Douglas's pouch, so that the solution might flow in the opposite direction to the extravasated stomach contents, thus minimising the risk of spreading the infection. The operation caused very little shock and the patient made a good recovery. In Mr. Roughton's opinion irrigation could hardly be performed satisfactorily without turning out the small intestines; it was important to start in Douglas's pouch.—Mr. SPENCER remarked that difficulties existed in the tympanites which ensued in the intestines and the strain on the mesentery.

Mr. J. D. MALCOLM narrated a case of Complete Removal of a Multilocular Cyst of the Pancreas, with colo-colic anastomosis 16 days later, followed by recovery. The patient was a woman, aged 50 years. A malignant growth of the left kidney was diagnosed but at the operation a multilocular cyst of the tail of the pancreas was discovered and removed. Healing caused no trouble but symptoms of a partial obstruction of the intestine developed and the abdomen was reopened on the sixteenth day after the operation. The difficulty existed at the splenic flexure and an anastomosis between the transverse and descending colons was effected, after which there were no further urgent symptoms. The tumour, which was to be preserved in the Museum of the Royal College of Surgeons of England, was exhibited. It was a multilocular cystoma with a small amount of solid structure between the cysts. The fluid was not examined. The solid growth, as described by Mr. S. G. Shattock, showed in parts an adenomatous and in parts a carcinomatous structure. Another case[1] in which a similar tumour was removed by Mr. Malcolm was referred to; also one published by Mr. Watkins Pitchford[2] and one recorded by Dr. Reginald H. Fitz.[3] The last named had collected eight cases, all those of "benign" multilocular cysts of pancreatic origin which he could find; some of these showed no new growth of any kind. A case published by Dr. F. H. Dunning[4] resembled the one now recorded by Mr. Malcolm in many details. The rarity of these tumours was noted, the two removed by Mr. Malcolm and that from the case recorded by Mr. Watkins Pitchford being the only specimens in the Museum of the Royal College of Surgeons of England. The question of their origin was discussed and Professor Ambrose Monprofit's[5] case, in which it was necessary to remove the tail of the pancreas and the spleen to complete the operation, was referred to. The tumour in this case was said to arise from the remains of the Wolffian body because of its structure. But on some grounds many of the foregoing cases could be attributed to the pancreas as the seat of their development. Mr. Malcolm's first case contained fluid which was strongly amylolytic and the structure of the second was very suggestive of that of the pancreas. The difficulty of diagnosis was discussed, most of the cases having been regarded as renal or ovarian tumours before operation. Complete removal was held to be the only rational treatment when it was possible, as drainage of a multilocular cystoma, especially if it should be malignant, was a futile procedure.—The PRESIDENT referred to a case in his experience which was mistaken for an ovarian tumour. The pancreas had to be cut through and a troublesome pancreatic fistula ensued. Tumours which could be lifted out of the abdomen like that narrated by Mr. Malcolm must be extremely rare.—Mr. MALCOLM, in reply, expressed the belief that the pancreas could be cut through as fearlessly as any tissue without very serious risk of fistula.

OPHTHALMOLOGICAL SOCIETY.

Congenital Malformed Cystic Eye.—Radium in the Treatment of Rodent Ulcer.—Implantation Tumour of the Iris containing Wood Fibres.—Exhibition of Cases and Specimens.

A MEETING of this society was held on May 3rd, Mr. J. PRIESTLEY SMITH, the President, being in the chair.

Mr. S. JOHNSON TAYLOR and Mr. E. TREACHER COLLINS contributed clinical and pathological accounts of a Cystic Swelling occupying the position of the Left Eye and apparently formed mainly by a forward bulging of the conjunctiva of the upper lid. It was present at birth and steadily increased in size. Mr. Taylor first saw the child when three weeks old and then tapped the cyst with a fine trocar and cannula. It refilled the following day. When next seen, about a year later, it had increased in all dimensions, standing out two and a half inches from the orbital rim and giving a most unsightly appearance. Some discharge and blood had also been coming away from its apex for two months. Mr. Taylor therefore operated under a general anæsthetic and succeeded in removing it in its entirety. Mr. Collins stated that the pathological examination of the specimen showed that the cyst was really due to an enormous distension of the whole globe. The outer fibrous tissue wall appeared to be sclerotic and in places much attenuated. The inner coat corresponded to the retina but nowhere did that portion of it which is normally developed from the inner layer of the secondary optic vesicle lie in contact with that developed from the outer layer. The anterior portion of the cyst was lined by the former—i.e., tissue composed of a delicate network of fibres with branching cells having nuclear bodies amongst them. The posterior part of the cyst was lined by the latter—i.e., a single row of epithelial cells deeply pigmented in places and in others unpigmented. The cavity of the cyst was composed of the space between these two layers (the cavity of the primary optic vesicle). The explanation of the formation of this cyst was apparently the imperfect involution of the primary optic vesicle to form the secondary optic vesicle. There had been some attempt at involution both anteriorly and below. Anteriorly the inner wall of the cyst was prolonged backwards in a fold at the bottom of which was a rudimentary lens. So at one stage there must have been some downgrowth of surface epiblast. Below, the cavity of the cyst was considerably encroached upon by a mass of atypically developed vitreous humour. The expansion of the cyst below must have been checked by this upgrowth of mesoblast, hence the chief distension was upwards into the upper lid. As the whole of that portion of the retina which normally forms its inner layers was at the anterior part of the cyst it is not surprising that no optic nerve developed. The lens presented a defect in the formation of its posterior capsule. Through the gap in it mesoblastic tissue had extended forwards, becoming mixed with the lens fibres. A nodule of hyaline cartilage was met with in the sclerotic at the posterior part of the specimen. The principal pathological features were illustrated by lantern slides.—Mr. W. H. H. JESSOP referred to the hardness of cataract in microphthalmic eyes which was probably due to this admixture of mesoblastic tissue with persistence of the hyaloid artery. He mentioned one case in which the entire contents of the globe had been removed in an attempt to withdraw the lens by forceps.

[5] Gazette Medicale de Paris, March 12th, 1904.

Mr. J. MACKENZIE DAVIDSON gave a brief *résumé* of cases of Rodent Ulcer treated by exposure to Radium. In 1896 Becquerel discovered the effect of uranium on photographic plates protected from ordinary light rays. The investigations of Madame and Professor Curie culminated in the discovery of radium, a metal of the barium series obtained from the residue of pitch-blende, which emitted rays of three kinds: (*a*) those which might be stopped by a sheet of paper and which did not penetrate the glass tube but gave rise to scintillation; (*b*) those which corresponded with the x rays within the tube, which penetrate glass but not lead or platinum; and (*c*) those equivalent to the extreme of penetration of x rays, capable of passing through several inches of glass and even metal. These last were the specially effective rays. The first application of radium for rodent ulcer was in the vicinity of the tear-sac where x rays were inapplicable or had failed. The ulcer, about an inch in diameter, was completely cured in five applications. Radium shaken down to the bottom of a thin glass tube was applied to the diseased area for about half an hour at a time. No sensation was felt, but in about eight days there was some reaction with formation of a crust and pus. Fresh applications were made at intervals of a month or six weeks. The cases cited were 14 in number, half in men and half in women. All were completely cured, the number of exposures varying from one to 12, repeated at intervals of from four to six weeks. The speaker said the tubes of radium underwent no change themselves and having been once procured were permanent—a great advantage in comparison with x ray tubes. He spoke of the excellent results obtained but insisted on the necessity of complete cure, as if patients desisted before this was effected they were prone to relapse.—Mr. M. S. MAYOU stated that when ulcers were so deep as to affect the bone they were intractable to this mode of treatment.—Mr. T. J. P. HARTIGAN said the first case of the kind treated and published in this country was one at the Hospital for Diseases of the Skin, Blackfriars, in 1903. Nearly 6000 such applications had been made there since. He questioned whether there were not some variations in quality or radio-activity in different specimens of radium and recommended the employment of celluloid rather than glass for the tube. 23 cases of rodent ulcer had been so treated without a failure and the method had been extended to cases of Paget's disease and psorospermosis and also to superficial carcinoma with excellent results. There were six cases now showing no sign of the disease.—Mr. DAVIDSON, in reply, said cases did not improve when the disease extended to the bone, otherwise the radium treatment might be regarded as a specific for rodent ulcer. He preferred glass for the retainer as it cut off the burning rays and he had a piece of platinum wire fused into the sealed tube to act as a conductor to prevent electric explosion. Moisture weakened the radio-activity and radium was still very costly, about £10 per milligramme.

Mr. R. PICKARD described with the aid of lantern slides an Implantation Tumour of the Iris which contained wood fibres. The patient was a girl, aged 14 years, and the tumour had been noticed for nine years. It was three millimetres in diameter and was situated below the pupil. On removal the basis was found to be granulation tissue containing three wood fibres of coniferous origin (displaying bordered pits). The tumour consisted of epithelial cells and contained several cysts, some of which were formed by degeneration of cells and others by the occurrence of fissures. There was no direct history of injury to the eye or trace on the cornea. Probably a fine splinter perforated the cornea ten years before when she fell and struck her nose against a table.

The following cases and card specimens were shown:—

Mr. SYDNEY STEPHENSON: A case of High Myopic Astigmatism, showing Fissures in Descemet's Membrane.

Mr. G. WINFIELD ROLL: Coloboma of the Choroid.

Mr. A. L. WHITEHEAD: An unusual case of Tumour of the Iris.

Dr. F. W. EDRIDGE-GREEN: (1) Apparatus for Estimating Hue Perception; and (2) a Spectroscope for Monochromatic Patches.

Dr. RAYNER BATTEN: Recurrent Orbital Tumour after Œdema of the Orbit.

Mr. W. I. HANCOCK: Tubercle of the Conjunctiva.

Mr. G. H. GOLDSMITH: Concussion Hole at the Macula.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.

Presidential Address.

THE jubilee meeting of this society was held on May 11th, Sir SHIRLEY F. MURPHY, the President, being in the chair.

After alluding to the interest attaching to the present meeting as falling within 48 hours of the fiftieth anniversary of the foundation of the society, the PRESIDENT referred to the circumstances that led to the institution of medical officers of health. It had been recognised that the great mass of the poor lived under conditions incompatible with a healthy existence, that these bred disease, and disease and misery fostered a spirit of discontent that was becoming dangerous to society and the State. The inquiries conducted by Edwin Chadwick, Southwood Smith, Neil Arnott, and James Phillips Kay led to the first public health legislation in 1848 when the General Board of Health was constituted. The Board did good work in the collection of evidence and statistics until in 1854 the duties were taken over by a department of the Privy Council since transferred to the Local Government Board. Under this Act the larger towns were empowered to appoint medical officers of health, which Liverpool had done under a local Act of the previous year. The first appointment under the Act was that of John Simon to the City of London. In 1855 the Metropolis Local Management Act made these appointments incumbent on all the vestries and local boards and next year 47 medical officers were appointed, among whom were Letheby (in succession to Simon), Burdon Sanderson, Odling. Pavy, Bristowe, Ballard, and a little later G. Buchanan, destined to succeed Simon at Whitehall. After a preliminary meeting at the house of Dr. Pavy the Society of Metropolitan Medical Officers of Health was formally inaugurated on May 13th, 1856, at the house of the Medical Society, under the presidency of Mr. Simon. Committees were appointed for various lines of investigation, as trades nuisances, adulteration of food, etiology of preventable diseases, statistics, meteorology and so on. Medical certification of the causes of death was not then compulsory but they exerted themselves to obtain information as to the causes, immediate and remote, the sanitary conditions of the houses, and the prevalence of sickness, but for various reasons the returns from public institutions were not continued for more than a year. Though it had not yet been found possible to establish a regular system of registration of all cases of sickness it was already felt that the issue of weekly returns of all cases of notifiable infectious disease should enable the medical officer of health of to-day to take steps for the repression of an outbreak that would be already beyond control when one or more deaths had occurred. The labours of these committees, with the advantages derived from the greater accuracy and completeness of the returns of the Registrar-General, gave an enormous impetus to inquiry and research, and in these and the few following years Dr. Snow's investigation of the means by which cholera was spread, with special reference to the behaviour of the epidemic of 1848 and 1854 in the districts of the Chelsea and Southwark Water Companies, the general recognition of the difference between typhus and typhoid fevers, the spread of the latter by means of milk, the aerial diffusion of small-pox, first suggested by Dr. Hillier in 1862, the differential diagnosis of scarlet fever and diphtheria, and the duty of State intervention in the conduct of trades and manufactures injurious to health with which the name of Dr. Ballard would always be associated effected little less than a revolution in the sanitary administration of the country. The appointment of medical officers of health in the provinces and rural districts, though optional until the passing of the Public Health Act of 1875, was becoming more general every year, affording many opportunities for investigating the means by which communicable diseases were spread. Another report of milk-borne disease, this time scarlet fever, was received in 1867 from Mr. Taylor of Penrith and was followed by so many from all quarters that its possibility and indeed its frequency were amply demonstrated. In 1877 and 1878 the like causation of outbreaks of diphtheria was proved by Mr. E. L. Jacob, a Fellow of the society, and Mr. W. H. Power, who, with the help of Dr. Klein, followed up the inquiry experimentally, proving with complete success that not only did the milk act as a simple vehicle of the infection from man to man, but that the cows themselves might suffer from modified forms of human diseases, imparting them to man with their normal characters. In 1886 Mr. G. Turner, medical officer of health of East Herts combined district, recognised diphtheria in a fatal disease of cats occurring simultaneously with diphtheria in man. Thus the medical officer of health could no longer ignore the diseases of the lower animals or the study of parasitic organisms. Within the last few years the labours of Manson, Bruce, Ross, and Nuttall in this country, with others on the Continent and in America, had shown the important part played by protozoa in the etiology of disease, parasites requiring an intermediary host in which to pass one phase of their life cycle. Though malaria had been practically stamped out and yellow fever and trypanosomiasis failed when imported to be communicated to other persons because the intermediary hosts could not live in our climate, the liability of rats to contract the plague and the connexion of the cimex with relapsing fever which was epidemic in these islands in 1868–69 could not be ignored. In 1841 the Registrar-General had applied the name "zymotic" to certain diseases but it was not until 1857 that Pasteur began his researches into the connexion of fungi with disease, identifying the cause of pebrine as Pollender and Davaine did that of anthrax. During the following years Villemin proved the infectivity of tubercle and the science of bacteriology grew up in the hands of Koch, Klebs, Löffler, Eberth, Gaffky, and others, who between 1876 and 1884 identified and cultivated the bacilli of tubercle, cholera, typhoid fever, diphtheria, &c., to which Kitasato in 1894 added plague, as others had those of pneumonia, influenza, meningitis, &c. Between 1886 and 1890 Salmon, Roux, Ehrlich, Behring, and Kitasato, working with sterilised cultures of hog cholera, tetanus, anthrax, and diphtheria, and more recently Haffkine, Yersin, Roux, Pfeiffer, Koch, and Wright, with those of typhoid fever, cholera, and plague, succeeded in rendering animals immune to these diseases, but the greatest triumph had been the antitoxin obtained by Behring through the inoculation of horses with virulent cultures of diphtheria, now used for preventive and curative purposes on man. Many forms of immunisation, permanent or temporary, were at present under examination—active or direct, by inoculation with living bacteria, by bacteria killed by heat, or attenuated by lesser degrees of heat, desiccation, or passage through another animal, or by bacterial extracts; and passive or indirect, when the toxins were neutralised by the inoculation of substances known as antitoxins produced in an animal that had been previously immunised in the direct method; and lastly, antibacterial serums which were still on their trial. Another line of research was that followed by Sternberg and Metchnikoff between 1881 and 1884 on phagocytosis or the ability of the leucocytes to devour and to destroy the bacteria as an explanation of normal resistance to infection, and by comparing the phenomenon as exhibited in the serums of a healthy person and of one suffering from tuberculosis the phagocytic index furnishing a measure of the probability of ultimate recovery of the latter. Ehrlich's side-chain theory and Wright's of the existence of opsonins increasing the susceptibility of the bacteria to phagocytosis were among the most recent contributions to this complex question. Ehrlich, von Behring, Metchnikoff, and many others were working at the problems of the transmission of immunity by the mother to her offspring in utero or through her milk, and the employment of the Gruber-Widal test for this purpose pointed the way to further discovery. Turning from scientific investigations in the laboratory to practical administrative work the President referred to the progress made in the protection of water-supplies from sewage pollution and in the prevention of the spread of typhoid fever through the specific contamination of shell-fish. Discussing the failure of the provision of isolation hospitals, on which enormous sums had been spent, and the universal enforcement of notification to "stamp out" infectious diseases, he referred to the influence of mild unrecognised cases and of "carriers," or persons who, though escaping themselves, conveyed the infection to others; to the observations of Whitelegge, Longstaff, and Newsholme on recurring waves of greater or less virulence and fatality which might or might not coincide with the recurring waves of prevalence, and to the apparent failure of preventive measures as at present practised to influence the prevalence of some diseases as showing that there must be causes at work still unknown to us which would if discovered help to explain the variations in severity and prevalence of diseases, as whooping-cough and measles, against which no measures were or could be taken. After discussing the various questions connected with the propagation of tuberculosis in the adult and the infant by inhalation and by ingestion, the relations of human and bovine disease and tuberculous milk, the inhalation of the dried spores and the prohibition of spitting, and Flügge's recent observations on the greater activity of "cough spray," which if ignored rendered all other precautions unavailing, he concluded by asking what practical and palpable results had been achieved during the last 30 or 40 years by the efforts of sanitary reformers. The mortality from tuberculosis had in 50 years been reduced by half, but a considerable reduction had already taken place before its infective character had been recognised or any measures had been undertaken to prevent its spread. There was no evidence of lessened activity of the bacilli. Had the resisting power of the population been increased by better food, clothing, and housing? There was no question that the standard of living of the masses had been greatly raised and the opsonic index showed the effect of better food, &c., on individuals. There might be some truth—how much one could not say—in Newsholme's theory of the benefit to the community from the segregation of persons who in their homes had been foci of infection. After paying a tribute to the good work of Dr. B. A. Whitelegge and his staff in the control of industrial diseases, the President turned to the evidence afforded by the returns of the Registrar-General as to the reduction of the death-rate between 1851–60 and 1891–1900. This had fallen no less than 18 per cent.—16 per cent. for males and 20 per cent. for females. Between the ages of five and 20 years it had fallen no less than 50 per cent. but between those of 45 and 75 years it had actually increased. Dr. W. Ogle ascribed this to the reduction of the earlier age periods having led to the survival of a generation of feebler individuals who would formerly have died young, but a careful study of the variations at each successive age period indicated that this cause was ceasing to act and the older individuals were becoming healthier than they were 20 years ago. Taking the popular division of diseases into preventable and non-preventable, it appeared that the reduction of the death-rate from the former was 42 per cent. but that of the latter only 4 per cent. The decline of the former was evident at all ages, that of the latter at the earlier only, for after 35 years they were increasing. A little while ago the increase began at 25 years and if this improvement continued it might be hoped that in another 50 years the reduction at advanced ages would be nearly as great as at the earlier. There was no apparent decrease in the infant mortality, but in St. Pancras Dr. J. F. J. Sykes had shown that a general improvement was masked by an increase confined to the first week. Did this point to ante-natal conditions? The decrease in the birth-rate, a phenomenon of far-reaching meaning, demanded careful consideration and it was remarkable that the death-rate in the most insanitary areas in East and Central London declined as alien immigrants superseded the original population. As a rule, however, the infant mortality varied inversely as the number of rooms in each tenement. Death-rates generally followed overcrowding with all its attendant evils, except the mortality from cancer, which though almost confined to past middle life was wholly independent of social position or sanitary conditions and they might venture to hope that by improved standards of living the physical condition of the nation might be enormously improved, though perfection was unattainable.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Patients.—An Infants' Milk Depôt.—Inguinal Hernia in the Female.

A MEETING of this society was held on May 2nd, Professor WILLIAM S. GREENFIELD, Vice-President, being in the chair.

Professor P. EHRLICH of Frankfort was elected an honorary member of the society.

Mr. H. ALEXIS THOMSON showed a man, aged 60 years, who suffered from Chronic Jaundice and Distended Gall-bladder, with relief of symptoms after cholecystenterostomy. He said that Courvoisier's law stated that 90 per cent. of cases of persistent jaundice were not due to impacted gall-stones but to malignant disease. On opening the patient's abdomen no evidence of malignant disease was found but the gall-bladder held about a pint of fluid. Lest drainage would be required permanently the gall-bladder was joined to, and opened into, the small intestine. The man went steadily downhill for some weeks. On going home, however, he treated himself by the "violet cure" for three or four months and was now quite well. The case was probably one of an inflamed condition of the head of the pancreas so compressing the head of the common bile duct as to cause obliteration of its lumen.

Mr. J. M. COTTERILL showed a lad suffering from Aneurysmal Varix of the Right Orbit. Six months ago he fell out of a vehicle, striking his left occipital region, and three days later his right eye began to project. The sight was reduced to one-tenth of the normal. The angioma concerned the ophthalmic artery and its branches. Treatment by electrolysis was out of the question. If operation were to be performed Mr. Cotterill would prefer ligature of the common carotid.

Dr. W. ROBERTSON, medical officer of health of Leith, read a communication entitled "The Practical Side of an Infants' Milk Depôt." He said that, in spite of his knowledge of the weaknesses and shortcomings of such institutions, he still believed in the value of the municipal milk depôt. It had been, and still was, said that the milk depôt was merely a clumsy cloak for an impure milk-supply. A pure ideal milk-supply ought to come from cows fed on rich pasture land; cows, milkers, dishes, and pitchers must be scrupulously clean and chilling of the milk should be carried out. In Edinburgh and Leith the dairymen were in most cases unwilling to move out of their beaten track or to put in operation what they were pleased to term "fads of health officials." They preferred to add formalin or boric acid rather than to chill the milk. The utmost vigilance was required to prevent adulteration by the addition of water, skimmed milk, and preservatives. In Leith a few selected cases were taken to court, as experience had shown that only glaring instances of adulteration were likely to result in a conviction. In Glasgow the least aberration from the milk standard was met by an adequate fine. Obviously, in the east of Scotland adulteration was encouraged and it had developed into a fine art. Last year an outbreak of diphtheria in Leith was traced to a dairy in which several cows were suffering from a teat eruption. The dairyman was asked to isolate the affected cows and to destroy their milk. This he promised to do but there was no diminution in the number of cases notified at the end of the week and in each case milk was obtained from the suspected dairy. It was found that the milk from the affected cows was still being sold, as the "doctor had been talking nonsense." Relays of inspectors were stationed at the dairy premises for a fortnight and they saw that every drop of suspected milk was poured into a drain and coincidently the epidemic was checked. Dr. Robertson was in entire agreement with the idea that cowsheds should not be found in towns. The dairyman knew perfectly well how important it was to groom cows and to have clean hands to milk the animals; he knew that cooled milk would keep sweet in the warmest weather and up-to-date dairymen sold milk in clean bottles. As soon as the public was taught to insist upon chilled milk delivered in bottles the dairymen would meet the demand. It was a mistake to think that an elaborately built cowshed was necessary to insure a pure milk-supply: with a wooden shed a pure milk could be, and was in practice, furnished. The motive power was the intelligence of the dairyman himself, but beyond must be the momentum of public clamour. The medical officer of health could only administer laws and make suggestions. It rested with the medical practitioner to teach his patients that what was best for them and their offspring was a milk-supply collected under what might be termed aseptic precautions. It was to counteract gross pollution on the one hand and ignorant methods of feeding on the other that the present-day milk depôt was established. The long septic feeding tube was done away with, methodical feeding was taught, and in general mothers were afforded an object lesson in correct principles of feeding. Gross neglect in feeding was the prime factor in causing so many fatal cases of diarrhœa. As regards the milk, speaking generally, it was necessary to be content with an impurity of at least 12,000 bacteria per cubic centimetre. That was looked upon as a standard supply of clean milk. The milk for the Leith depôt was obtained from a dairy farm near Haddington where the cows were for the greater part of the year fed upon natural pasture and where every precaution was taken to insure a clean supply. At the depôt water, cream, and sugar were added, the proportions varying with the ages of the children to be fed. As a rule the fat varied between 3 and 3·4 per cent. The bottles, after being filled, were placed in the steriliser and kept at a temperature of 180° F. for 20 minutes and then placed in a tank of cold water. When the depôt was first opened an attempt was made to sterilise the milk. It was subjected to a temperature of 212° for 30 minutes (a preliminary half-hour being required to reach this degree of heat). The procedure was unsatisfactory because the prolonged heating frequently caramelised the milk; besides the milk was not sterile and two cases of scurvy occurred amongst those using this milk. These cases seriously affected the depôt in the eyes of the public for some time. Inquiry showed that the milk was lamentably deficient in fat. Since the mere pasteurisation of the milk and the addition of fat had been practised no cases of scurvy had arisen. Of the bottles of milk prepared at the Leith depôt only 15 per cent. were found to contain sterile milk. The bacteriology of milk accounted for the difficulty in inducing sterility. Roughly, three groups of organisms were present in milk—namely, (1) those belonging to the bacterium coli, proteus, and lactic acid group which were easily killed by short exposures to heat; (2) butyric acid organisms, anaerobic and spore-bearing, which caused rapid decomposition of milk with coagulation and gas formation and required a temperature of 212° maintained for an hour or one and a half hours in order to kill the spores; and (3) the bacillus subtilis or peptonising group which was the prime cause of summer diarrhœa. The spores of group 3 required exposure for two hours at 212° before they were killed. Pasteurisation did not alter the taste of the milk and inflicted as little damage on it as possible. The children fed on milk supplied by municipal depôts were regularly visited by lady health visitors and in Glasgow a lady practitioner had been appointed to give her undivided attention to this work. Weighing of the infant was of great value. Pasteurised milk did not agree with every infant. For young infants each meal was so small that the system was decidedly unpopular. The popular quantities were those found in bottles prepared for babies of two months of age. Amongst the infants fed on depôt milk during 1904 there were no deaths from diarrhœa, while among other hand-fed infants there were 36 deaths. In 1905 three infants fed on depôt milk died from diarrhœa, while of infants not fed on the milk 49 died from diarrhœa.

—Dr. W. LESLIE MACKENZIE said that the state of milk separators which were being cleaned out gave a good idea of the dirty condition of milk, for they contained a deposit from a quarter to half an inch thick, consisting of mud, mucus, straw, &c. He drew att [illegible] the great benefit shown in Paris, Dundee, and els [illegible] ing free meals to suckling mothers. In Paris, of 401 mothers so fed less than 1 per cent. of the children suckled by them died, whilst the mortality in Edinburgh was from 18 to 20 per cent. —Dr. MALCOLM CAMPBELL said that he had fed 37 children for four months with milk obtained from the Leith depôt and among them there was only one death. The infants were weighed once a week and only five showed no increase during one week. After a time there was great rivalry amongst the mothers as to which child put on most weight.—Dr. J. STRACHAN (Dollar) said that his practice was to feed the infants on whole cow's milk without any change and his mortality was exceedingly small. He had no greater trouble with babies so fed than with breast-fed infants. He encouraged the use of one cow's milk, as it lessened the risk of mixing and so varying the composition. He had frequently met with babies starved on mixtures of milk and water who immediately began to thrive on pure cow's milk. He saw no reason for adding water to milk.

Dr. E. W. SCOTT CARMICHAEL read a paper on Inguinal Hernia in the Female. He said that this variety was of very common occurrence in females. Of 184 radical operations performed by him in children in this variety of hernia 23 were females and the relative frequency of this hernia did not seem to vary with age. There was good reason for concluding that this form of hernia was congenital in the female as well as in the male. The right side was most frequently the site of the affection. The contents of the sac in 28 cases were as follows: Fallopian tube and ovary in 17, Fallopian tube alone in five; small intestine in two; omentum in two; cæcum, ovary, and Fallopian tube in one; and vermiform appendix, ovary, and Fallopian tube in one. In two cases the sac was tuberculous. It was suggestive that the persistence of the canal of Nuck should be associated so frequently (over 30 per cent.) with malposition of the ovary and Fallopian tubes. The frequency of the presence of the ovary and Fallopian tube in the sac was most probably connected with the development of the inguinal ligament, while in the adult the presence of the ovary in the sac was due to mechanical effect. The ovary and tube did not lie free in the sac as a loop of intestine did, but were intimately associated with its wall, one broad ligament springing directly from the posterior aspect of the sac. A large percentage of inguinal herniæ in the female were bilateral and this seemed to be more marked the younger the subject The younger the patient the more frequently were the ovary and tube found in the sac. In order to replace the ovary and tube it was necessary to divide freely the attachment to the sac. Tuberculous disease of the sac occurred in about 3 per cent of herniæ in young subjects. Dr. Carmichael drew the following conclusions from his experience: (1) inguinal hernia in the female child occurred in about 10 per cent. of all cases; (2) it was associated in 30 per cent. of cases with a descent of the ovary and Fallopian tube; (3) the presence of these organs was often associated with malformation and defects of the genital system; and (4) the condition most likely to be confused with a hernia containing the ovary was the presence of a tuberculous nodule in the sac.

EDINBURGH OBSTETRICAL SOCIETY.—A meeting of this society was held on May 9th, Dr. J. W Ballantyne, the President, being in the chair.—Professor Robert Jardine (Glasgow) read notes of two cases of Eclampsia One of the patients died from suppression of urine caused by complete infarction of both kidneys; the other recovered after having had upwards of 200 fits. The first patient was in the seventh month of her seventh pregnancy and was admitted to the Glasgow Maternity Hospital after having had eight fits. A few days before swelling of the legs and face had been noticed and the patient had complained of severe headache On admission she was unconscious and very restless; the urine became almost solid on boiling and contained granular tube casts Blood to the amount of 12 ounces was drawn from the arm; two pints of saline solution, consisting of one drachm of sodium chloride and one drachm of sodium acetate in a pint of water, were transfused, the stomach was washed out, two ounces of salts were administered, and a hot pack was applied. She had three fits soon after admission and a drachm of bromide and half a drachm of chloral were given by the stomach tube. The hot pack was repeated and the skin acted well. The bowels acted four times with salts. Next day she passed urine freely, which contained 10 per 1000 albumin (Esbach) and 1½ per cent of urea. On the following day she gave birth to a seven months fœtus. From midday there had been almost complete anuria; such urine as had been passed in the morning gave only 2 per 1000 albumin (Esbach). The day after the labour she had one fit. Two pints of the same saline solution were infused under the right breast and into the abdominal wall. Suppression of urine was evident and this was treated by cupping, pilocarpine injections, hot packs, &c. These caused profuse perspiration. Finally, after consultation, as the suppression was due to congestion, the right kidney was operated on, the capsule was incised and stripped off one side and slightly off the other, and an incision one-third of an inch deep was made into the kidney substance. The patient stood the operation well but her pulse failed and she died ten hours after the operation, about five and a half days after the commencement of the suppression. At the necropsy both kidneys were found to be enlarged and congested. The right kidney, which had been operated on, had a layer of blood clot between the capsule and the kidney substance varying in thickness up to a quarter of an inch. The cortex was found to be intensely congested with blood with changes of the nature of a widespread infarction. An almost identical case of complete suppression of urine was reported by Dr. W. S. A. Griffiths and Dr. W. P. Herringham in March in the *Journal of Pathology and Bacteriology*. This patient had suffered from chronic renal disease for years; there were no fits Only ten ounces of urine were passed in nine days. Another case is reported in the same journal (1898, Vol. V., p. 197), where the suppression had lasted seven days without any uræmic symptoms. In the second of the two cases now described by Professor Jardine the patient was in the ninth month of her fourth pregnancy. She had had eight fits before admission to the Maternity Hospital. She had slight œdema of the legs and the urine showed a cloud of albumin, with some epithelial cells but no casts. Under chloroform, two pints of the same saline solution were infused under the right breast; the stomach was also washed out. She remained well for two and a half days, when a child was born naturally. Fits began two days after the delivery and continued until over 200 in all had occurred. She was treated by bleeding and transfusion twice; by injection of morphine given while the kidneys were acting freely; and by chloral and bromide. Lumbar puncture was also performed and half an ounce of cerebro-spinal fluid was withdrawn; it came away in drops but during a fit it ran quite freely; the fluid was quite clear and was found by culture and under the microscope to be quite sterile. Two hours later lumbar puncture was again performed and one-fifth of a grain of cocaine was injected. This seemed to quiet the patient but the fits did not diminish in frequency. Strychnine and digitalin were given to keep up the strength. The kidneys were extremely active all the time, a circumstance which favoured elimination of the poison.—Dr. A. H. Freeland Barbour read notes of a case of Broad Ligament Cyst with twisted pedicle and extravasation of blood into the cellular tissue along the left ovarian vein. He said that cases of hæmorrhage on the distal side of a twisted pedicle into the tumour itself were of common occurrence but cases of hæmorrhage on the proximal side were rare. The patient, who was unmarried and 40 years of age, was found to have a solid tumour pushing the uterus upwards and another in the lower region of the abdomen, apparently cystic. On opening the abdomen a cyst growing between the layers of the broad ligament was found with a half twist in its pedicle. On its removal it was noted that the broad ligament contained an extravasation of blood. A large fibroid tumour was found in the pouch of Douglas and was easily removed as its pedicle was only of the thickness of a pencil. Two litres of salt solution were left in the abdomen. The patient died from acute septic bronchitis supervening on bronchitis with emphysema. The necropsy showed that there was no pelvic peritonitis.—Dr. Barbour also read a note of a case of Abdominal Hysterectomy for Inversion of the Uterus, with fatty degeneration of the inverted portion.—Dr. E. W. Scott Carmichael read a paper on Hernia of the Uterine Adnexa

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on May 8th, Mr. Justice Walton, the President, being in the chair.—Dr. T. Claye Shaw read a paper on Insanity and Murder. He said that most murders were committed in moments of strong mental emotion; from the medical standpoint the prisoner's sanity or insanity was the most important element in the incident. In 1904 45 per cent. of the patients at the Criminal Lunatic Asylum

(Broadmoor) had been charged with murder; in that year 40 per cent. of those tried for murder were found to be insane at some period after arrest; in 1903 the percentage was 25·6. The present method of procedure in such murder cases was illogical, undignified, and incongruous. It might be assumed in practice that insanity and irresponsibility coexisted; the responsibility of patients which apparently was recognised in asylums was both specious and at times expensive. The rule in Jersey was to notify all lunatics to the authorities; it might be considered by us. Where the sanity of remanded prisoners was questioned by the medical officer he reported his suspicion to the Treasury which at once sends down a mental specialist for a consultation; at the subsequent trial a jury was sworn with the sole object of trying the issue of insanity, which being proved postponed the trial, for the prisoner was returned "insane on arraignment." Some prisoners resented the plea of insanity from fear either of being sent to Broadmoor or of losing the chance of a speedy acquittal; thus also might facts concerning collusion and agency be stifled. Dr. Shaw proposed that before the trial proper commenced sworn evidence should be taken as to the prisoner's sanity. The prison surgeon could testify in obvious cases; otherwise two official mental experts nominated by the Treasury would appear. Such evidence should be final but at the judge's discretion an inquiry might issue as to who did the deed and how it was done. In this way, it was affirmed, much unseemly medical dispute would be obviated at a later stage of the trial.—Dr. Henry Maudsley did not agree that the present procedure was at fault nor was it unfavourable to the prisoner. All medical reports were placed unreservedly in the hands of the defence. The proposed procedure would deprive the accused man of the right to adduce evidence in support of his sanity; this hardship, however, occasionally happened now even with minor criminal allegations and was in great contrast with the formalities necessary prior to the seclusion of a lunatic. No practical injustice was done; the jury leaned towards the prisoner's favour and might even decline to credit the medical evidence of sanity. 40 years ago evidence of insanity was likely to be received with suspicion and distrust both by judge and jury.—Dr. T. S. Clouston, from a long experience in Scotch criminal procedure, agreed in substance with the proposals. The experts appointed by the Treasury should have full access not only to the prisoner but to all the available circumstances of the crime and the persons connected with him and it. The judge should be allowed to call a medical assessor to his aid during the trial. It was anomalous that the Home Secretary acted upon unsworn testimony as to the patient's mental condition after a formal trial and conviction. The proposed Court of Criminal Appeal might review convictions where mental disorder had probably caused the prisoner's offensive conduct.—Dr. C. A. Mercier did not regard insanity and irresponsibility as convertible terms. Each was a matter of degree; many "irresponsible" persons deserved punishment, notably those whose criminal deeds were not influenced by their madness. The onus of deciding on the sanity of the accused would be shifted from the judge and jury to the two experts who themselves might disagree. The prisoner if found insane would be barred a verdict of acquittal. In this country trial by experts would never be allowed to replace trial by jury. There was no grievance to be remedied; if the judge thought that further evidence of insanity could be adduced he could inform the prison authorities of his opinion privately.—Dr. James Scott deemed the present procedure, which was not perfect, to be preferable to the proposed change. In some men the crime itself was the only symptom of insanity available. Mental experts examining the prisoner after the trial were not fettered by the rules which prohibited the extraction of self-incriminating testimony. Some patients at Broadmoor objected that, as they had not been found guilty of a misdeed, they should be discharged at once. It was not logical to restrict the proposed innovation to murderers.—Dr John Baker said that prisoners were discharged from Broadmoor at the discretion of the Home Office after petition by the prisoner or his friends and a report by the medical officer; there were no rules as to the length of detention, not even with puerperal offenders. He had noted that many who entered Broadmoor, when asked concerning their alleged criminal act pleaded amnesia; this state was often merely assumed but it was also true that it required a tremendous mental effort to reconstruct the details of a terrible act. Convicts were kept separated from the other patients; it was a very awkward position to be in when challenged by these latter as to why they should not be liberated, since nothing criminal had been proved against them.—Dr. Robert Jones favoured the retention of the present procedure; insanity was often a matter of opinion and could not be established even by post-mortem methods; the brief sittings usually possible in the case of prisoners made a definite conclusion very uncertain in many criminal inquiries.—Dr. T. B. Hyslop held that while the medical faculty had to determine questions of sanity, responsibility was beyond their scope. Trained lawyers excelled medical men in sifting details.—Dr. F. S. Toogood urged that many cases would have to be investigated immediately after the commission of the crime as where delirium tremens was a factor. At the Lewisham Infirmary he received many persons discharged as "cured" from the London County Asylums.—The learned President did not approve of the suggested interference with the Royal Prerogative as administered by the Home Secretary who was able to secure and to review all the evidence available, including such facts as had been excluded during the trial by legal technicalities; further he believed that juries, though at times acting illogically, seldom went very wrong. At present a prisoner might be tried both as to his fitness to plead and afterwards as to his guilt. If it was found that then and there he did not appreciate what was going on in court, his trial was postponed. Dr. Shaw had proposed that he should be dealt with after two "certificates on oath" of experts who might possibly fail to agree; this would not be trial, for no evidence would be laid before persons competent to decide the facts in issue. He feared that juries were sometimes biased by hearing the horrid details of a crime, so that they determined that someone must be punished, usually the prisoner before them. On the other hand, it was not always merciful to insanity, with the resulting prolonged seclusion at Broadmoor instead of alternatively an acquittal or a short sharp sentence; with some habitual inebriates such a detention after a crime was the best possible treatment of the disease.—Dr. R. J. Collie, Dr. S. R. Wells, and Mr. F. Danford Thomas also spoke.—In his reply Dr. Shaw said that it surprised him to hear that his suggested procedure would be unpopular with the public.

DERMATOLOGICAL SOCIETY OF LONDON.—The annual general meeting of this society was held on May 9th, Dr. J. J. Pringle being in the chair. The following officers were elected for the ensuing session:—*Council*: Dr. H. G. Adamson, Mr. Willmott H. Evans, Dr. T. Colcott Fox, Dr. James Galloway, Mr. Malcolm Morris, Dr. J. A. Ormerod, Dr. J. J. Pringle, Dr. Edward Stainer, Dr. J. Herbert Stowers, and Dr. Norman Walker. Honorary treasurer: Dr. H. Radcliffe Crocker. *Honorary secretaries*: Dr. Arthur Whitfield and Dr. E. G. Graham Little.—An ordinary meeting was afterwards held, when the following cases were exhibited.—Mr. T. E. A. Pearman, introduced by Dr. Galloway, showed a case of Unilateral Partial Œdema in a child, aged two and a half years. There was an œdematous condition of the left thigh and leg which caused this limb to be double the size of that on the right side. There were also slight œdema of the left cheek and a fulness of the bridge of the nose, which was also probably œdematous.—Dr. F. Parkes Weber said that he was familiar with this condition and with the literature on the subject. It was a congenital lymphatic œdema, sometimes occurring in segments of the body, as in this case, and sometimes symmetrically. The general prognosis was not bad. Meige had written on it in the Salpêtrière magazine and references were given in the *Presse Médicale* of the past year.—Dr. J. M. H. Macleod showed a boy, aged eight years, the subject of Adenoma Sebaceum of a very characteristic type. The face was covered with small very red papules with numerous telangiectases scattered over the surface. There were further characteristic nævoid fibromata upon the back and the forehead. The boy had had fits in early life and was now quite idiotic. There was a history of fits in the mother also but this was the only child out of four who had adenoma sebaceum.—Dr S. E. Dore also showed a case of Adenoma Sebaceum in a man, aged 26 years, in whom the disease had not shown itself apparently until the age of 21 years. The eruption was much less marked than in the previous case and consisted only of pinpoint-sized pale papules for the most part, with a few very red larger papules upon the alæ of the nostrils. The patient's mental condition seemed normal. In addition to the papules above described he had mall nævoid fibromata upon the back and loins. The case vas pronounced to be a somewhat abnormal one of adenoma ebaceum.—Dr. Whitfield showed a case of Linear Lichen Planus upon the right thigh and buttock of a girl, ged seven and half years, the disease having commenced four months previously. There were no lesions upon any other part of the body.—Dr. Pringle showed a case for diagnosis of a man who was covered with a superficial, very red, in places yellow, Eruption, slightly scaly, and not at all infiltrated. It had persisted for four years but there had not been any severe itching. The general health had not suffered. The blood had been examined and showed a slight degree of leucocytosis but no leucocythæmia.—Dr. Radcliffe Crocker considered the case to be a typical example of the disease which he had named xanthoerythrodermia perstans.—Mr. Evans showed a case of Actinomycosis of two and a half years' duration in a woman, aged about 40 years. She had a large amount of scarring in the neck and side of the face The disease had apparently started with the tonsil. Much benefit had resulted from the administration thrice daily of 15-grain doses of potassium iodide. The characteristic fungus had been found in the discharge.—Dr. Adamson showed a case for diagnosis of a boy, aged seven years, with numerous pitted scars arranged in close juxtaposition upon the lower part of the abdomen over an area of about six inches. Within this area there were some hard papules as well which, in combination with the scars, suggested the diagnosis of a tuberculide. The condition had persisted for three years.—Dr. J. H. Sequiera showed a case for diagnosis of a young woman, aged 19 years, who had a Granulomatous Infiltration of the Nose and Cheek, Leucoplakia, and some large deeply Pigmented Scars upon the Right Thigh, the last lesions having existed from the age of two years. There were *corneal nebulæ*, but these were pronounced by an ophthalmic surgeon to be due to ulceration, not to interstitial keratitis, and there was no choroiditis. There were no marks of syphilis in the teeth. The case was shown as one in which it was difficult to discriminate between tuberculosis and syphilis and it was even suggested that both diseases might be present at the same time The general opinion was that the case was an unusual one of congenital syphilis showing tertiary lesions.—Dr. Little showed a case of Erythema Keratodes in a middle-aged man who had suffered from this affection for at least three years. The sole of the right foot was occupied for its posterior half by a very much raised hard keratotic mass, with a wide pink areola surrounding it. The left foot remained unaffected. The condition had been painful but was relieved by treatment.

BRITISH GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held on May 10th, Mr. F. Bowreman Jessett, the President, being in the chair.—Mrs. M. A. D. Scharlieb read a paper entitled "The Advantages of the Abdominal Route in Operations for Cancer of the Uterus." She said that a large percentage of women suffering from cancer of the uterus sought advice too late; many were not examined and a still larger number were believed to be free from the disease because the vaginal portion appeared to be healthy. If the operator was equally dexterous in operating by the vagina and by the abdomen the only probable advantage of the former was the diminution of post-operative shock. Operation through the abdomen secured: (1) a more fully exposed and convenient field of operation, (2) a better opportunity for breaking down adhesions without injury to the bladder or intestines; (3) more adequate examination and removal of pelvic glands, especially of those lying along the course of the iliac vessels, and about the bifurcation of the aorta; (4) less danger to the ureters, which might be examined and preserved uninjured while the cellular tissue was dissected away and the uterine vessels were tied on their outer side; (5) more trustworthy hæmostasis, the vessels being easily ligatured, which was a great improvement on the use of clamps, for the latter were always liable to bruise the tissues and had been known to cause necrosis and secondary hæmorrhage: (6) more easy separation of the bladder and rectum and less likelihood of injury to them; (7) the possibility of dividing the vagina low down, which was a great advantage when the disease had spread to the walls of this tube; and (8) economy of time in operating and the fact that cases which were inoperable by the vaginal route might be successfully completed by the abdominal one, more especially when the vagina was long, narrow, and rigid, as in elderly virgins and nulliparæ. It was not to be expected, however, that these advantages would be conceded by those who had practised vaginal hysterectomy for the last 20 years and whose technique was almost perfect. All would deplore the appalling percentage of inoperable cases and gladly exchange an operability of 15 per cent. for one of 60 per cent. In comparing results it was not fair to make a comparison of the results of an operation reserved for the most advanced cases with those of an operation done in less advanced cases. The parametric tissue required removal and the plan of splitting the broad ligament had much to commend it, as the uterine artery and ureter could be reached from the wall of the pelvis. A list of 21 consecutive cases was given, of which 20 made an immediate recovery, while none had yet reached the five years' limit.—Mr. A. W. Mayo Robson said that at an early stage the supravaginal operation would yield good results. As soon as the disease had extended to the body of the uterus he was clearly convinced that it was better to operate by the abdominal route. It was necessary to teach patients that if they would seek advice early they might be cured of conditions which would otherwise prove fatal.—Mrs. Stanley Boyd said that if operators saw the case as soon as they wished any good operation would succeed.—Dr. J. A. Mansell Moullin said that the treatment of cases of cancer must largely depend upon the nature of the case and the bias of the operator.—Dr. Ferdinand A. Purcell advocated the vaginal route where the disease was in the cervix, but when it had extended to the body of the uterus he considered that the abdominal route was to be preferred and that panhysterectomy was the operation of selection.—Miss Louisa B. Aldrich-Blake said that she preferred the abdominal method in all cases and quoted from 34 cases where she had operated in this manner.—The President said that the situation of the growth ought to be taken into account in determining the nature of the operation. In cases of disease of the body he preferred the vaginal method.

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—A meeting of this society was held on May 4th and was devoted to the exhibition of pathological specimens, Mr. G. Pernet being in the chair.—Dr. E. Hobhouse (Brighton) showed a specimen of Congenital Pyloric Stenosis from an infant, aged six weeks. A day was selected for performing an operation but the child died the night before.—Dr. E. C. Mackay exhibited a specimen of Cerebrum with a Tumour situated in the anterior half of the right side which was probably *glioma*.—Dr. Edmund Cautley exhibited a Specimen of Congenital Laryngeal Stenosis from a child, aged five months, the epiglottis being folded on itself longitudinally so that the superior aperture was much narrowed.—Dr. G. A. Sutherland exhibited a skull affected with Congenital Syphilis and Hydrocephalus; it showed well marked craniotabes, also the results of intracranial drainage for hydrocephalus. The skull had contracted until the bones were over-riding.—Mr. A. N. Leathem exhibited a specimen of the Stomach showing Ulceration round the Pylorus covered with Diphtheritic Membrane.—Dr. J. G. Emanuel (Birmingham) showed three specimens of Congenital Deformity of the Heart. In the first (lent by Dr. G. W. Powell) the aorta and pulmonary artery arose from a single ventricle, which was probably the right one. All the valves were normal. In the second (lent by Dr. O. J. Kauffmann) the aorta arose from the right ventricle and the pulmonary artery from the left and the foramen ovale was widely open; this specimen was from a boy, aged 11 years. In the third (lent by Dr. T. Stacey Wilson) the membranous part of the inter-ventricular septum was absent and the aorta arose as much from the right as from the left ventricle.—Dr. F. Langmead exhibited a specimen of Primary Sarcoma of the Lung removed from a girl, aged five years. The signs during life were those of pleural effusion. No growth was found elsewhere. He also exhibited a microscopical section from a girl, aged eight months, showing many Tubercle Bacilli from the base of a gastric ulcer.—Mr. Pernet exhibited microscopical sections of Nævi Cystepitheliomatosi Disseminati (lymphangioma tuberosum multiplex). This, he said, was a very rare disease consisting of numerous small tumours situated about the upper part of the front of the chest mainly but also on the back and face. The specimen was obtained from a woman, aged 25 years, in whom the growths were said to have appeared at the age of 16 years. The histological appearances were small cysts with colloid contents and strands and aggregations of cells which Mr. Pernet considered were of epithelial origin. He also exhibited a drawing and photograph of Racial Pigmentation on the buttocks of a Siamese baby received from Mr. J. D. Gimlette of Kelantan, Siam.—Dr. G. Carpenter exhibited a Tuberculous Kidney removed by operation from a girl, aged ten years.—Mr. H. S. Clogg exhibited specimens of Fibro-Sarcoma and Angio-Sarcoma from the Parotid Gland.

Leeds and West Riding Medico-Chirurgical Society.—A meeting of this society was held on May 4th, Mr. Edward Ward being in the chair.—Dr. Adolph Bronner (Bradford) read a paper on the Modern Mastoid Operation. He said that the size and position of the mastoid cells and of the lateral sinus varied very much, and it was impossible to know how far the disease had spread before the parts were exposed. In most chronic cases it was necessary to perform the complete mastoid operation—namely, the opening up of all the mastoid cells, the attic and antrum, and the removal of the posterior wall of the osseous meatus. A large smooth-walled cavity should be formed consisting of the middle ear, attic, mastoid antrum and cells. The chisel should be used as little as possible, as there was danger of splitting the bone and damaging important parts and the concussion produced was dangerous to the brain, especially as there was always the possibility of an undiagnosed brain abscess. Suitable bone forceps and gouges were most useful and should be employed as much as possible. The electric burr was not now used so much as formerly. The treatment of the soft parts was important, as there was danger of stricture of the cutaneous meatus. Dr. Bronner generally adopted Stacke's or Ballance's method of making a flap from the posterior wall of the meatus. In cases where much bone had been removed skin-grafting was useful. In ordinary cases complete healing could be induced without grafting in from five to eight weeks. He never closed the posterior wound directly after the operation but left it open for a few days and at first dressed the wound daily. He thought it was an unsurgical proceeding to close up a foul septic wound and only to drain through the meatus. He used iodoform powder for a few days and then xeroform and plugged with aluminium gauze. Iodoform if used for any length of time caused excessive growth of granulation tissue. The application of peroxide of hydrogen was useful during the operation and also in the after-treatment.—Mr. Harold Upcott read a paper entitled "A Study of Epithelial Tumour of the Prostate," based on the examination of 33 specimens removed by operation. He said that in 27 of the specimens the enlargement was due to adenomatous or fibro-adenomatous growth; in five carcinoma was revealed by the microscope, and in only one was the change purely fibrous. The overgrowth of glandular tissue might give rise to one or more localised enucleable tumours, or, when arising from numerous foci, might cause a fairly symmetrical enlargement, affecting mainly the lower poles of the lateral lobes, its growth occurring chiefly in a forward direction. Of the cancerous prostates, two had been removed in fragments, two were but slightly enlarged and were shelled out whole, while the fifth was markedly enlarged. Malignant disease of the prostate could not be diagnosed in the majority of cases except by microscopical examination; to the naked eye the scirrhous cancer resembled the simple fibrous prostate, while a prostate affected with a more cellular growth might be indistinguishable from an adenomatous prostate.—Mr. M. A. Teale showed a case in which Landman's Wire Artificial Vitreous was Introduced into the Cavity of the Left Sclerotic four weeks ago.—Dr. A. S. F. Grünbaum (with Dr. O. C. Gruner) showed a specimen of Parotid Epithelioma Invading the Spinal Canal; and (with Dr. R. D. Smedley) Spirochæta Pallida in the Ape.—Cases and specimens were also shown by Mr. G. Constable Hayes, Mr. W. H. Brown, Mr. E. Ward, Dr. Gruner, Mr. B. G. A. Moynihan, Mr. R. Lawford Knaggs, Mr. E. Robinson, Dr. T. Churton, Mr. J. F. Dobson, Mr. H. Littlewood, Dr. E. F. Trevelyan, and Dr. W. H. Maxwell Telling.

Otological Society of the United Kingdom.—A meeting of this society was held on May 7th, when a discussion on Fixation of the Stapes was opened by Dr. Urban Pritchard. He divided the forms of fixation of the stapes into the following: 1. Fibrous: (*a*) due to fibrous bands, chiefly in the pit of the stapes; and (*b*) due to a solid mass of organised and hardened granulation tissue. 2. Osseous: (*a*) from ossification of the annular ligament in the course of otosclerosis; and (*b*) from ossification of organised granulation tissue. Fixation of the stapes was, he said, in any form absolutely fatal to return of good hearing. There was no known treatment of any avail in osseous fixation and fibrous fixation by a solid mass of new tissue presented almost the same difficulties to treatment. The prognosis and treatment in fixation by fibrous bands were a little more hopeful. Something could be done by forcible inflation, by iodides, and by direct mechanical mobilisation.—Dr. Thomas Barr described the differential diagnosis of fixation of the stapes as it occurred: (1) from otosclerosis; (2) from adhesive middle-ear catarrh; and (3) from purulent processes in the middle ear. In simple uncomplicated cases due to otosclerosis differentiation during life was not attended with much difficulty. Differentiation from labyrinthine affections rested on tuning-fork tests. Information might be derived from making a window opening in the posterior superior quadrant of the tympanic membrane and he considered it important that more work should be done in securing anatomico-pathological confirmation of conclusions derived from clinical observations during life.—Mr. Richard Lake described cases of fixation under the headings of false or true. False he described as represented by (1) fixation of the malleus; (2) fixation of the malleus, with changes in the vestibule and the oval window; and (3) changes due to sclerosis of the mucous membrane in the vestibule—(*a*) as part of a general sclerosis of the air passages and (*b*) as the result of post-inflammatory trouble in this region. True fixation, he considered, as (1) the result of chronic suppuration, and (2) the result of rarefying osteitis of the labyrinthine capsule.—Dr. Albert Gray considered that fixation of the stapes was not, properly speaking, a pathological entity, as it might be the result of injury to the stapedio-vestibular articulation, of suppuration spreading into the joint from the tympanum, or from bony changes in the capsule of the labyrinth.—Mr. L. A. Lawrence considered that Gellé's test was not trustworthy in the diagnosis of ankylosis and suggested that paracusis was due to vibration and not to increased noise, instancing the fact that a patient with this symptom heard better when driving in a rubber-tyred hansom than in one with iron tyres.—Dr. J. Dundas Grant drew attention to the frequency of otosclerosis in anæmic young women and in osteo-arthritic patients.—Mr. Yearsley pleaded for uniformity of tuning-fork tests and their more general use in reporting cases.

Pathological Society of Manchester.—A laboratory meeting of this society was held on May 9th. The meeting was devoted to a demonstration of specimens and methods, of which the following were shown.—Dr. W. B. Anderton: Mixed Tumours.—Dr. E. M. Brockbank: Some Varieties of Red Blood Corpuscles.—Dr. J. Cameron: The Cytological Changes in the Cell Nuclei of Embryonic and Malignant Tissues.—Dr. A. Hill Griffith: Tuberculosis of the Iris.—Professor I. Walker Hall: Various.—Dr. Loveday: The Determination of the Opsonic Index.—Dr. Mair: Hodgkin's Disease simulating Pernicious Anæmia.—Dr. J. Dixon Mann: (1) Various Urinary Pigments with their Spectroscopic Reactions; and (2) Bilicyanin, a Disputed Fæcal Pigment.—Dr. S. Moritz: A New Urine Saccharimeter.—Dr. D. Orr and Dr. R. G. Rows: Various Lesions of the Central Nervous System.—Dr. D. Lloyd Roberts and Dr. W. E. Fothergill: Illustrations of Gynæcological Pathology.—Dr. Roberts: Primary Tracheal Diphtheria in an Adult.—Professor J. Lorrain Smith: A Peculiar Reaction in Lardaceous Tissues.—Dr. S. Powell White: (1) Lipoma in a Parrot; (2) Renal Carcinoma in a Rabbit; (3) Myeloid Sarcoma in a Drake; and (4) Carcinoma of the Thyroid in a Mouse.

Harveian Society.—A clinical meeting of this society was held on May 10th at the Paddington Infirmary. Dr. Maurice F. Squire showed the following cases: 1. Hæmorrhage into the Right Crus Cerebri. The patient was a woman, aged 57 years, who fell down on getting out of bed and remembered nothing more until the next day. On admission to the infirmary there were complete paralysis of the muscles supplied by the right third nerve, paresis of the left face, arm, and leg, with deviation of the tongue to the left. Her condition improved so that she could partially open the right eye, but now movements of the left eye were impaired so that she could not move it beyond the middle line in either direction. The discs were normal. 2. Periostitis of the Humerus in a child, aged three years. A twin brother had a similar affection in one arm. 3. Infantile Paralysis in a child, aged two years, affecting the anterior tibial muscles of the right leg. 4. A case of Sprue in a man, aged [illegible] The patient was a soldier who had been eight years in India where he had had "continued fever." The present illness started six months after return home in 1904 with vomiting and diarrhœa which had persisted on and off ever since. On admission in April, 1905, there were emaciation, denudation of epithelium of the tongue, and copious offensive light-coloured stools. (The case was discussed by Dr. W. H. Willcox who had found a milk diet beneficial in a similar case.) 5. A case of Scleroderma in a man, aged 43 years. The disease had commenced at the age of 14 years. There were patches of scleroderma on the shins, feet, thighs, and arms. 6. Carcinoma of Pylorus with secondary growth in the liver in a man, aged 45 years. 7. A case of Myopathic Dystrophy. 8. Dislocation of the Sternal End of the Left Clavicle in a man, aged 70 years, who was knocked down by a van, the wheel of which passed over his chest and fractured the second and third ribs on the left side as well.—Dr. Willcox showed a case of Rheumatoid Arthritis in a boy, aged ten years. Two years ago he complained of pain in the hands and feet and gradual thickening of the joints took place. There was now marked thickening on the inter-phalangeal joints in both hands with limitation of movement and also thickening of the interphalangeal joints of the toes. The hands and feet were always cold and turned blue in cold weather. The patient frequently suffered from chilblains.—The case was discussed by Dr. W. Winslow Hall and Dr. H. J. Macevoy.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on May 9th, Dr. M. Mackintosh, the President, being in the chair.—Dr. G. F. McCleary, the medical officer of health of the borough of Hampstead, read a paper on the Decline in the English Birth-rate and its Causes. He observed that the phenomenon of a declining birth-rate was to be seen in most civilised countries. In England the birth-rate had fallen from 35·3 in 1873 to 27·2 in 1905, and there was reason to think that the decline would continue. 10 per cent. of the decline was due to the decrease in illegitimacy, 20 per cent. to a decrease in the marriage-rate, and 70 per cent. to lessened fertility of married women. The latter was due in part to alterations in the age constitution of the population of married women at child-bearing ages, which now contained a greater proportion of older married women than in former years; to the use of artificial means to prevent conception; and possibly to an increase in involuntary sterility. It was not unreasonable to suspect that the function of maternity had to some extent been undergoing atrophy in the modern Englishwoman; for in recent years there had been (1) a decline in lactation; (2) an increased infantile mortality from premature birth; and (3) a decrease in the proportion of male births. It was important that the decline in the birth-rate should be studied by medical men, for it was not improbable that the profession might be called upon to make an authoritative statement on some aspects of the subject. The birth-rate was a matter of special concern to the people of this country, for our colonies, though vast in extent, were poor in population and the colonists of British blood were not fertile. The birth-rate in some of the Australian colonies and amongst the English Canadians was little higher than that of France and unless the British became more fertile it was doubtful whether the British empire would long remain British in anything but name.

Reviews and Notices of Books.

Wharton and Stillé's Medical Jurisprudence. Vol. II.: Poisons. By ROBERT AMORY, A.M., M.D., and ROBERT L. EMERSON, A.B., M.D. Fifth edition. Rochester, N.Y.: The Lawyers' Co-operative Publishing Co. 1905. Pp. 858.

IN presenting the fifth edition of this well-known work the knowledge of the action of poisons upon the living organism as demonstrated by the more recent literature published in Europe and America has made it necessary for the editors to make a complete change in the classification of the groups of poisons adopted in the former editions. The older writers on the subject of toxicology were inclined to classify poisons in groups indicated by similar symptoms following their administration. The editors consider that this method tends to confusion and consequently they have deemed it better to classify poisons more in accordance with their chemical and physical relations. An expert familiar with chemistry, when investigating the matters removed from the body of a person who is supposed to have met his death by poisoning, or in examining solid or liquid food, matters that might be so contaminated, naturally pursues a regular order of chemical analysis; his researches, therefore, would be more readily assisted by reference to a work arranged according to a chemical classification. This is perfectly correct if the book is intended mainly for laboratory work but for reference by a medical practitioner we believe that the old classification would prove more serviceable.

Much of the work of the former editors of previous editions has been retained in the present issue. The most important judicial cases, some of which were to be found in the text of the previous editions, have now been placed in the appendix. This is a good procedure, as the insertion of full accounts of such cases in the general body of the work is likely to interrupt the continuity of the description of the action of the poison. The portions of this edition which relate more especially to chemical research have been thoroughly revised and obsolete methods for the detection of poisons have been replaced by processes which have borne the test of the more recent advances in that science.

In reading the work it soon becomes apparent that the editors have spared no trouble to render it as complete as possible. From the large number of references in the footnotes it is evident that the compilation of the views of the various authorities on toxicology covers a wide field of research and that much patience and perseverance are required to sift the vast amount of literature that has accumulated during recent years. Attention is especially directed to the action of the more recent forms of poisons commonly used in the industrial arts, such as carbolic acid and wood alcohol, and a chapter has been introduced on ptomaine poisoning caused by food. For convenience of reference every chapter is divided into sections each of which is numbered, the numbers running consecutively from the commencement of the book. A very full and complete index is given, the various subjects being indicated by the numbers of the sections in which they will be found and not by those of the pages; the required information can therefore very readily be obtained. The whole work is an excellent one and deals most thoroughly with the subject of toxicology. It will be found especially useful by those practitioners who are engaged in medico-legal work either as coroners or as experts.

The Rheumatic Diseases. By J. ODERY SYMES, M.D. Lond., D.P.H., M.R.C.S. Eng., L.R.C.P. Lond., Assistant Physician and Bacteriologist, Bristol General Hospital. London and New York: John Lane, the Bodley Head. 1905. Pp. viii.–233. With 23 illustrations. Price 5s. net.

THIS volume, the first of a series entitled the Practitioner's Handbooks, deals with those affections of the joints to which the descriptive adjectives "rheumatic" and "rheumatoid" are commonly applied. In his introduction Dr. Symes points out that there is an increasing tendency to restrict the use of the word *rheumatic* to such conditions as are excited by a specific micro-organism—the diplococcus rheumaticus. At the same time until the causation of all those forms of arthritis associated with various acute infective processes has been clearly established he is of opinion that it is convenient to retain the common names for them, such as gonorrhœal rheumatism and scarlatinal rheumatism. Unfortunately, the term "rheumatic" has been also used to indicate conditions caused by exposure to cold whereby considerable confusion has resulted. Consequently the sooner

nised forms in the "De Simplici Medicina." Naturally information is almost as valuable to botanists as to ical scholars, whilst folklore and superstitions of various s are frequently illustrated. The book concludes with xcellant bibliography and indices of modern names and he Arabic words enumerated in the work.

JOURNALS AND MAGAZINES.

he Edinburgh Medical Journal.—In the May number P. McBride discusses Hysterical Deafness, pointing out difficulty of diagnosis in this condition—a difficulty only red up, indeed, when the affection disappears. Mr. n S. McArdle writes of the Radical Cure of Inguinal nia, noting the importance of leaving the inner surface the abdominal wall perfectly smooth and of bringing n the oblique and transversalis muscles to Poupart's ament as well as the conjoined tendon; and Mr. B. G. A. ynihan records some instances of violation of the so-called aw of Courvoisier"—viz., that in calculous obstruction the common bile-duct the gall-bladder is not enlarged, ereas in obstruction due to other causes enlargement is rule. Dr. Purves Stewart contributes an interesting per on the Clinical Significance of the Cerebro-spinal uid, especially in the early diagnosis of tabes dorsalis and neral paralysis.

The Scottish Medical and Surgical Journal.—Perhaps the st interesting paper in the May number of this journal is at by Dr. J. Eason on Paroxysmal Hæmoglobinuria. In it supplements his former observations, pointing to the teraction of two bodies—a complement and an intermediary body—in producing hæmolysis in this affection. d brings forward evidence that the action of cold is necesry for the attachment of the intermediary body to the ood corpuscles. Dr. A. A. Scot Skirving contributes an ticle on Oral Syphilis, in which the importance of proibiting smoking in cases of such disease is insisted upon nd a plea made for the more frequent use of the inunction ethod of administering mercury. Dr. A. Dingwall Fordyce rites of the suprarenal glands in various affections and ome notes on gynæcological matters are contained in a aledictory address delivered by Dr. N. T. Brewis to the dinburgh Obstetrical Society.

The Medical Chronicle.—The May number opens with an nteresting paper by Professor W. Osler on Angina Pectoris s an Early Symptom of Aneurysm of the Aorta, suggesting hat this symptom depends on structural changes in the walls of the vessel. Dr. Arnold W. W. Lea points out the possibility and also the utility of drainage of the peritoneum through the vagina in young children and Dr. R. T. Williamson writes on the treatment of diabetes mellitus, dvocating aspirin as a useful remedy in mild cases and giving some hints as to diet.

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on May 10th, Sir ICHARD DOUGLAS POWELL, Bart., K.C.V.O., the President, eing in the chair.

The following Members who had been elected to he Fellowship at the last meeting were admitted as ellows:—Dr. Samuel Walton Wheaton, Dr. Frederick Villiam Barton-Fanning, Dr. John Hill Abram, Dr. George enkell Drummond Robinson, Dr. Richard Tanner Hewlett, r. Ernest Graham Gordon Little, Dr. Charles Richard Box, r. Maurice Craig, Dr. James Purves Stewart, Dr. Thomas rves Horder, Dr. James Hugh Thursfield, and Dr. Edward arquhar Bernard.

The PRESIDENT announced that he had nominated Sir illiam S. Church and Dr. G. A. Heron as representatives of the College on the general committee of the Second International Congress on School Hygiene to be held in London from August 5th to 10th, 1907.

A communication was received from Mr. Reginald Blunt, asking permission to photograph the portrait of Dr. Messenger Monsey, in possession of the College, to illustrate his forthcoming book on "Chelsea" which deals particularly with the physicians of the Royal Hospital.—The request was granted.

A report was read from Dr. Frederick T. Roberts, representative of the College on the court of governors of the University of Sheffield, on a meeting of the court which had recently been held.

Dr. Norman Moore was re-elected the representative of the College in the General Council of Medical Education and Registration. The PRESIDENT thanked Dr. Moore for the services which he had rendered to the College in acting as its representative and Dr. MOORE replied, thanking the College for his re-election.

A report, dated April 24th, was received from the adjudicators of the Weber-Parkes prize for 1906, stating that no essays had been received.

A report, dated Feb. 12th, was considered for the second time from the committee appointed to prepare a revised edition of the College by-laws; the additions and alterations therein proposed were finally enacted.

The PRESIDENT then dissolved the Comitia.

Looking Back.

FROM

THE LANCET, *SATURDAY*, May 17th, 1828.

SPONTANEOUS COMBUSTION.

In the *Journal de Pharmacie*, there is a case recorded by Professor Rudolphi, of a man who suddenly felt a pain in the arm, similar to that produced by the blow of a stick, and immediately perceived in the same spot a small flame, which burnt his shirt. There is also the case of a girl mentioned, seventeen years of age, in whom a kind of bluish sulphureous flame appeared around the finger; the flame could not be extinguished by water: it burnt the clothing brought into contact with it, but could only be distinguished in the dark. The best electrometers placed in contact with the patient, presented no sign of electricity.

Nothing can be more empirical, than making disease subservient to remedies; but though truly unscientific, we every day see men who should know better, degrade themselves by following this line of practice. For example: one oculist will bleed, &c., in all cases of ophthalmia; form all artificial pupils on the principle of Gibson, and, in every case of cataract, operate with a needle; on the contrary, another man will use solutions, and ointments, as the only remedies for conjunctival ophthalmia; make pupils as recommended by Cheselden, and even attempt to extract membranous cataracts. In like manner, one surgeon is so devoted to the double circular incision, that he performs no other, though his coadjutor, in the same hospital, is bigoted to the double flap operation, and never amputates but after this manner. But, the unprejudiced practitioner will look to the nature of the case, and adjust means accordingly; for only by thus acting can he be of public utility, and honestly beneficial to himself.[1]

In a trial which took place in the county of Suffolk in 1808, Pizzy, a farrier, and another person, were indicted for administering medicines with an intent to produce abortion. It was proved on the trial, that the medicines failed in effecting the intended object, and that it was at length accomplished by mechanical violence. In consequence of the defective state of the law, which has made no provision in respect to manual operations, the criminal was tried for giving medicine which had no effect, whilst the means by which the crime had actually been perpetrated, were only admitted in evidence as proof of the intention with which the medicines were given![2]

---

[2] Foot note to a discussion at a meeting of the London Medical Society on the use of spurred rye and of digitalis.

THE LANCET.

LONDON: SATURDAY, MAY 19, 1906.

The Interim Report of the Antityphoid Inoculation Committee.

THE committee appointed by the Army Council to investigate the practical, prophylactic and therapeutic value of current methods of immunisation against typhoid fever has held six meetings since its inauguration on May 11th, 1904. Surgeon-General A. H. KEOGH opened the original proceedings on behalf of the Army Council, informing the members of the committee that it was not intended that they should undertake such investigation, "but for this purpose competent officers of the Royal Army Medical Corps should be detailed, the lines of their researches being laid down for them and their work being supervised by the committee." The committee, which consists of Dr. W. BULLOCH, Dr. F. FOORD CAIGER, Dr. JAMES GALLOWAY, Major W. B. LEISHMAN, R.A.M.C., Dr. R. BRUCE LOW, Dr. ALLAN MACFADYEN, and Professor A. E. WRIGHT, with Dr. C. J. MARTIN as chairman, proceeded to its work upon the lines suggested by Surgeon-General KEOGH, and has now issued an interim report setting forth the opinions arrived at and suggesting propositions as to further investigation. The object of this report is to satisfy the Army Council of the urgent need of this further investigation and of the necessity of providing the requisite machinery for carrying it out.

In this report the committee sets forth a list of all the documents bearing on the subject, containing all the available data relating to antityphoid inoculation; these consist of 16 reports, letters, original papers, and memoranda placed at the disposal of the committee by the Army Medical Department. The committee states that, having carefully considered the whole of the statistical material, it is satisfied that "the records which are available up to date furnish proof that the practice of antityphoid inoculations in the army has resulted in a substantial reduction in the incidence and death-rate from enteric fever among the inoculated." The committee further states that the statistical records support the scientific observations that the protective substances which are developed in the human organism after antityphoid inoculation are identical with those developed in the course of an attack of typhoid fever, and that animals can be rendered resistant to typhoid fever by the same process of inoculation as that used upon man. As a consequence of these conclusions the committee recommends that the practice of voluntary inoculation against typhoid fever in the army should be resumed. It also strongly urges the Army Council to provide facilities for the execution of the following investigations: First, investigations with the present form of vaccine (standardised typhoid cultures sterilised by heating to 60° C.) upon troops leaving for foreign service, with a view to determine the protective value of varying doses of vaccine, the number of doses to be administered, and also the duration of the protection conferred; secondly, investigations upon animals in order to improve the vaccine if possible; and thirdly, an investigation of the development of protective substances in the blood of patients suffering from, and convalescent from, typhoid fever. The committee recommends that these investigations should commence forthwith, and in its report proceeds to outline the necessary arrangements, which comprise (1) the inoculation under careful supervision, at least one month prior to embarkation, of volunteers from each regiment proceeding from this country to India, (2) the attachment of a junior officer of the Royal Army Medical Corps to each regiment to proceed abroad and to remain with it for at least three years, acting under the directions of the committee as regards the inoculations and the collection of statistics in connexion with them, and (3) the collection by the headquarters of the Army Medical Department of statistics relating to inoculations which may be carried out in addition to those on the above-mentioned selected units. It is further pointed out that the difficulties of the investigations proposed will, in the first instance at any rate, necessitate the active supervision of experts who have made a special study of this kind of research, and that owing to the scientific laboratories of the Royal Army Medical College being at present incomplete the vaccine should be derived from a source to be approved by the committee.

There is a minority report attached to the main report signed by Dr. BULLOCH and Professor WRIGHT, who, while agreeing with the conclusions and general recommendations of their colleagues, are of opinion that the temporary calling in of experts to the assistance of the army medical officers would fail to meet the requirements of the case. They suggest that a "*quasi*-permanent organisation" is necessary in order that the vaccine and the details of the inoculations may be continually modified in the light of information gained by research. We cannot but feel that this difference of opinion among the members of the committee is regrettable, as the distinction between temporary expert assistance, as suggested by the majority report, and "a *quasi*-permanent organisation" does not seem to be a very great one, especially when we are told that the proposed organisation should consist of "medical officers working in association with civilian experts." We think that Dr. BULLOCH and Professor WRIGHT might have agreed *in toto* with their colleagues, though we are certain that they considered the claims of science would be better served by their differing. With the conclusions of the committee and its recommendations we most cordially agree. A study of the statistics available in 1904 will show that the incidence of typhoid fever among the inoculated was reduced to at least one-half of that among those not inoculated, and a similar reduction was observed in the case mortality of those contracting the disease after inoculation compared with that among the non-inoculated. When the enormous losses which this disease causes in the army both in war and peace are taken into consideration—e.g., the deaths in India alone amount to half a battalion a year—the importance of the investigation of prophylactic measures becomes at once apparent, and we may express the hope that the Army Council will put the recommendations of the committee into effect as soon as the necessary organisation can be brought into being.

◆

The Scottish Universities and Autonomy.

WE published in THE LANCET of May 5th, p. 1266, an outline of the changes proposed to be made in the curriculum for the degree in medicine of the University of Edinburgh. The proposed changes had been accepted by the University Court and by the Senatus and were submitted to the meeting of the General Council of the University held on May 2nd, together with certain additions and amendments suggested by the business committee of the Council. At the meeting both the proposed changes and the suggested amendments were unanimously adopted, after being supported in the main by the Dean of the Faculty of Medicine, Professor D. J. CUNNINGHAM, and seconded by Sir JAMES RUSSELL, the Inspector of Anatomy for Scotland and an ex-Lord Provost of the city of Edinburgh. A letter was also read from the Principal of the University, Sir WILLIAM TURNER, in which no objection was taken to the amendments suggested by the business committee while approval of the claim for autonomy was specified. It might be thought that where there was practical unanimity on the part of the University Court, the Senatus, and the General Council of the University as to the desirability of making changes not of a revolutionary character in the medical curriculum there would be no difficulty in giving effect to such a unanimous opinion. Such, however, is far from being the case. All such proposals, emanating from any one of the Scottish Universities, have to be submitted to the other three, and it is competent for any one of them to notify dissent and to lodge a representation to that effect with the Privy Council, the Sovereign and the Privy Council being the court to which all proposed alterations have to be submitted. Even supposing that there is no difficulty with the Privy Council, the proposals have to be laid before both Houses of Parliament during 12 weeks to give an opportunity to Parliament to present an address praying the Sovereign to withhold assent. That such procedure is at its best slow and cumbrous was the opinion expressed by the business committee and endorsed by the General Council. It is even worse than this, for experience has shown that opposition from the sister universities may lead to almost indefinite delay owing to the desirability of mollifying the opposing universities and thus endeavouring to remove opposition. It may be assumed that the intentions of the framers of the ordinances, which begin to chafe the hands of the University of Edinburgh, were excellent and that the ordinances were suitable for the time when they were drawn. It may even be suggested that the fetters imposed by the ordinances have in the past been hugged with considerable self-complacence by all the universities, but it is worthy of special note now that at the recent meeting of the Edinburgh General Council the University of Edinburgh seems to have suddenly awakened from a condition of sopor which was thought, even by some of her well-wishers, to be one of coma and that, if she has not initiated, she apparently endorses a demand for greater freedom and for a large measure of autonomy.

When it is understood that the University had to face such a procedure as we have indicated it is not perhaps to be wondered at that it was difficult to stir her up to make the necessary effort to reform anything. That she should now seek emancipation from her bondage indicates, we venture to believe, that she feels the spirit of dissatisfaction which has been steadily growing with regard to education and that she perceives that she can only adapt herself readily to changing times and circumstances by obtaining practical autonomy. How great is the present bondage of the Scottish Universities will be appreciated when it is known that in the Faculty of Medicine, for instance, the University cannot divide a subject taught from one chair and have two professors instead of one, cannot alter the times at which students may sit for examination, or modify the grouping of the subjects on which they are examined, without a new ordinance which may have to struggle against the resistance of a sister university which either does not consider the proposed changes desirable or objects to advances which she is not in a position to adopt. It is a curious result of legislation to find it obstructing advance in one university because the other universities may not be in a position to advance equally. Such legislation was useful and at one time probably necessary to maintain the standard of Scottish University degrees, and the law framers cannot be greatly blamed for not foreseeing that the problems before the universities in the near future would be their adaptation and extension to meet the requirements of advances in knowledge rather than the exercise of a mutual check to prevent degradation or underselling. That the Scottish Universities now should be granted as great a measure of autonomy as has been given to the newer English Universities will not be seriously questioned, and it is probable that Parliament will be ready to grant a Bill for what is practically a dissolution of partnership, care being taken that examination standards are maintained. Such freedom would greatly favour the development of the individual Universities and would introduce an influence that would attract benefactions for the extension of teaching and of research. We are necessarily interested in all centres of medical instruction and in all measures having for their object the improvement of medical education and the advancement of medical knowledge, and now that Edinburgh has through her General Council declared her need of greater freedom it is hardly credible that she will not be strenuously backed by the other Scottish Universities and that she will not be supported in her demand by the medical and the lay press.

The Licence of Quackery and Superstition.

THE protracted inquiry into the death of Major JOHN NICHOLAS WHYTE which was held by Mr. TROUTBECK, the coroner for Westminster, during the early part of this month has been reported in full in many newspapers and with such details as have yet been published many of our readers are no doubt familiar. As the

THE LANCET.

LONDON: SATURDAY, MAY 19, 1906.

The Interim Report of the Antityphoid Inoculation Committee.

THE committee appointed by the Army Council to investigate the practical, prophylactic and therapeutic value of current methods of immunisation against typhoid fever has held six meetings since its inauguration on May 11th, 1904. Surgeon-General A. H. KEOGH opened the original proceedings on behalf of the Army Council, informing the members of the committee that it was not intended that they should undertake such investigation, "but for this purpose competent officers of the Royal Army Medical Corps should be detailed, the lines of their researches being laid down for them and their work being supervised by the committee." The committee, which consists of Dr. W. BULLOCH, Dr. F. FOORD CAIGER, Dr. JAMES GALLOWAY, Major W. B. LEISHMAN, R.A.M.C., Dr. R. BRUCE LOW, Dr. ALLAN MACFADYEN, and Professor A. E. WRIGHT, with Dr. C. J. MARTIN as chairman, proceeded to its work upon the lines suggested by Surgeon-General KEOGH, and has now issued an interim report setting forth the opinions arrived at and suggesting propositions as to further investigation. The object of this report is to satisfy the Army Council of the urgent need of this further investigation and of the necessity of providing the requisite machinery for carrying it out.

In this report the committee sets forth a list of all the documents bearing on the subject, containing all the available data relating to antityphoid inoculation; these consist of 16 reports, letters, original papers, and memoranda placed at the disposal of the committee by the Army Medical Department. The committee states that, having carefully considered the whole of the statistical material, it is satisfied that "the records which are available up to date furnish proof that the practice of antityphoid inoculations in the army has resulted in a substantial reduction in the incidence and death-rate from enteric fever among the inoculated." The committee further states that the statistical records support the scientific observations that the protective substances which are developed in the human organism after antityphoid inoculation are identical with those developed in the course of an attack of typhoid fever, and that animals can be rendered resistant to typhoid fever by the same process of inoculation as that used upon man. As a consequence of these conclusions the committee recommends that the practice of voluntary inoculation against typhoid fever in the army should be resumed. It also strongly urges the Army Council to provide facilities for the execution of the following investigations: First, investigations with the present form of vaccine (standardised typhoid cultures sterilised by heating to 60° C.) upon troops leaving for foreign service, with a view to determine the protective value of varying doses of vaccine, the number of doses to be administered, and also the duration of the protection conferred; secondly, investigations upon animals in order to improve the vaccine if possible; and thirdly, an investigation of the development of protective substances in the blood of patients suffering from, and convalescent from, typhoid fever. The committee recommends that these investigations should commence forthwith, and in its report proceeds to outline the necessary arrangements, which comprise (1) the inoculation under careful supervision, at least one month prior to embarkation, of volunteers from each regiment proceeding from this country to India, (2) the attachment of a junior officer of the Royal Army Medical Corps to each regiment to proceed abroad and to remain with it for at least three years, acting under the directions of the committee as regards the inoculations and the collection of statistics in connexion with them, and (3) the collection by the headquarters of the Army Medical Department of statistics relating to inoculations which may be carried out in addition to those on the above-mentioned selected units. It is further pointed out that the difficulties of the investigations proposed will, in the first instance at any rate, necessitate the active supervision of experts who have made a special study of this kind of research, and that owing to the scientific laboratories of the Royal Army Medical College being at present incomplete the vaccine should be derived from a source to be approved by the committee.

There is a minority report attached to the main report signed by Dr. BULLOCH and Professor WRIGHT, who, while agreeing with the conclusions and general recommendations of their colleagues, are of opinion that the temporary calling in of experts to the assistance of the army medical officers would fail to meet the requirements of the case. They suggest that a "*quasi*-permanent organisation" is necessary in order that the vaccine and the details of the inoculations may be continually modified in the light of information gained by research. We cannot but feel that this difference of opinion among the members of the committee is regrettable, as the distinction between temporary expert assistance, as suggested by the majority report, and "a *quasi*-permanent organisation" does not seem to be a very great one, especially when we are told that the proposed organisation should consist of "medical officers working in association with civilian experts." We think that Dr. BULLOCH and Professor WRIGHT might have agreed *in toto* with their colleagues, though we are certain that they considered the claims of science would be better served by their differing. With the conclusions of the committee and its recommendations we most cordially agree. A study of the statistics available in 1904 will show that the incidence of typhoid fever among the inoculated was reduced to at least one-half of that among those not inoculated, and a similar reduction was observed in the case mortality of those contracting the disease after inoculation compared with that among the non-inoculated. When the enormous losses which this disease causes in the army both in war and peace are taken into consideration—e.g., the deaths in India alone amount to half a battalion a year—the importance of the investigation of prophylactic measures becomes at once apparent, and we may express the hope that the Army Council will put the recommendations of the committee into effect as soon as the necessary organisation can be brought into being.

The Scottish Universities and Autonomy.

WE published in THE LANCET of May 5th, p. 1266, an outline of the changes proposed to be made in the curriculum for the degree in medicine of the University of Edinburgh. The proposed changes had been accepted by the University Court and by the Senatus and were submitted to the meeting of the General Council of the University held on May 2nd, together with certain additions and amendments suggested by the business committee of the Council. At the meeting both the proposed changes and the suggested amendments were unanimously adopted, after being supported in the main by the Dean of the Faculty of Medicine, Professor D. J. CUNNINGHAM, and seconded by Sir JAMES RUSSELL, the Inspector of Anatomy for Scotland and an ex Lord Provost of the city of Edinburgh. A letter was also read from the Principal of the University, Sir WILLIAM TURNER, in which no objection was taken to the amendments suggested by the business committee while approval of the claim for autonomy was specified. It might be thought that where there was practical unanimity on the part of the University Court, the Senatus, and the General Council of the University as to the desirability of making changes not of a revolutionary character in the medical curriculum there would be no difficulty in giving effect to such a unanimous opinion. Such, however, is far from being the case. All such proposals, emanating from any one of the Scottish Universities, have to be submitted to the other three, and it is competent for any one of them to notify dissent and to lodge a representation to that effect with the Privy Council, the Sovereign and the Privy Council being the court to which all proposed alterations have to be submitted. Even supposing that there is no difficulty with the Privy Council, the proposals have to be laid before both Houses of Parliament during 12 weeks to give an opportunity to Parliament to present an address praying the Sovereign to withhold assent. That such procedure is at its best slow and cumbrous was the opinion expressed by the business committee and endorsed by the General Council. It is even worse than this, for experience has shown that opposition from the sister universities may lead to almost indefinite delay owing to the desirability of mollifying the opposing universities and thus endeavouring to remove opposition. It may be assumed that the intentions of the framers of the ordinances, which begin to chafe the hands of the University of Edinburgh, were excellent and that the ordinances were suitable for the time when they were drawn. It may even be suggested that the fetters imposed by the ordinances have in the past been hugged with considerable self-complacence by all the universities, but it is worthy of special note now that at the recent meeting of the Edinburgh General Council the University of Edinburgh seems to have suddenly awakened from a condition of sopor which was thought, even by some of her well-wishers, to be one of coma and that, if she has not initiated, she apparently endorses a demand for greater freedom and for a large measure of autonomy.

When it is understood that the University had to face such a procedure as we have indicated it is not perhaps to be wondered at that it was difficult to stir her up to make the necessary effort to reform anything. That she should now seek emancipation from her bondage indicates, we venture to believe, that she feels the spirit of dissatisfaction which has been steadily growing with regard to education and that she perceives that she can only adapt herself readily to changing times and circumstances by obtaining practical autonomy. How great is the present bondage of the Scottish Universities will be appreciated when it is known that in the Faculty of Medicine, for instance, the University cannot divide a subject taught from one chair and have two professors instead of one, cannot alter the times at which students may sit for examination, or modify the grouping of the subjects on which they are examined, without a new ordinance which may have to struggle against the resistance of a sister university which either does not consider the proposed changes desirable or objects to advances which she is not in a position to adopt. It is a curious result of legislation to find it obstructing advance in one university because the other universities may not be in a position to advance equally. Such legislation was useful and at one time probably necessary to maintain the standard of Scottish University degrees, and the law framers cannot be greatly blamed for not foreseeing that the problems before the universities in the near future would be their adaptation and extension to meet the requirements of advances in knowledge rather than the exercise of a mutual check to prevent degradation or underselling. That the Scottish Universities now should be granted as great a measure of autonomy as has been given to the newer English Universities will not be seriously questioned, and it is probable that Parliament will be ready to grant a Bill for what is practically a dissolution of partnership, care being taken that examination standards are maintained. Such freedom would greatly favour the development of the individual Universities and would introduce an influence that would attract benefactions for the extension of teaching and of research. We are necessarily interested in all centres of medical instruction and in all measures having for their object the improvement of medical education and the advancement of medical knowledge, and now that Edinburgh has through her General Council declared her need of greater freedom it is hardly credible that she will not be strenuously backed by the other Scottish Universities and that she will not be supported in her demand by the medical and the lay press.

The Licence of Quackery and Superstition.

THE protracted inquiry into the death of Major JOHN NICHOLAS WHYTE which was held by Mr. TROUTBECK, the coroner for Westminster, during the early part of this month has been reported in full in many newspapers and with such details as have yet been published many of our readers are no doubt familiar. As the inquiry has been followed by a verdict of manslaughter, and as the accused is at the present moment under remand at the Westminster police court, we shall, of course, not be expected to comment upon any of the extraordinary and terrible features of the story. The prisoner is a qualified medical man, whose name remains upon the official roll of the profession but who has stated in the coroner's court that he has left the ranks of medicine to become a "Christian Scientist," and the question of his guilt or innocence must undoubtedly be complicated by the fact that he had once earned proper medical and surgical diplomas and had been engaged in the exercise of his calling in several responsible situations. Whether Major WHYTE actually died because of the treatment received at the hands of the "Christian Scientists" (perhaps we should say because of the neglect of treatment prescribed by that sect) will be decided by a court of law, and all the circumstances point to the legal investigation being of deep interest to the medical profession. They should be of corresponding interest to the public, for if Major WHYTE's death is found to be traceable to "Christian Science" the public might well be asked to notice the dangerous height to which distrust of the medical profession has been allowed to grow in this presumably educated country. This distrust has been implanted in the breast of the public by the many onslaughts which scientific medicine sustains at the hands not only of the purely venal quack but of our presumably educated classes. Major WHYTE, having a fractured spine, was snatched back from the gates of death by prompt surgical interference—the "Christian Scientists" themselves would probably allow this, for they are understood not to attempt the treatment of fractures, against the pain and deformity of which Mrs. EDDY's ritual is inefficacious. An operation of a dangerous and difficult character was successfully performed upon the unfortunate man; it resulted in the immediate saving of life and the opening up of a prospect of considerable prolongation of that life in circumstances which would not necessarily be unendurable. Major WHYTE, with whose desire to try all and every means that could restore him to health and vigour every one of us must sympathise without reservation of sort or kind, believed that "Christian Science" held out to him the opportunity that he sought. So he deserted medical procedure for the tenets of Mrs. EDDY and died in circumstances of the most appalling misery. The law will now decide how far that death, despite the unremitting attendance of his body-servant, was due to neglect of medical precautions by those who had taken the responsibility of treating his case. Such a story, whatever the outcome of legal procedure may turn out, would not be possible were it not for the tolerant attitude of men of education and authority, and of a large section of the press, towards the claims of quackery and towards the avowed opponents of medical science in all shapes. "Christian Science" is known to be a fad among rich and well-born people; a Member of Parliament has recently from his place in the House accused medical men of being pecuniarily interested in the death of their patients; men of a certain amount of education and position, as well as a few literary men and humorists, are found ready to stigmatise those who are engaged in the work of medical research as bloody-minded torturers; and the proprietors of certain newspapers receive with both hands money for the insertion of the grossest inventions of the charlatan. These are the things which have undermined the public trust in medicine; these are the things which have accustomed the wits of persons, otherwise sane, to believe that the purchased prayers of an ESTHER MARIA GRANT, uttered in deference to the expositions of a MARY BAKER G. EDDY, will work therapeutic marvels.

Annotations.

"Ne quid nimis."

THE ANNUAL DINNER OF THE PHARMACEUTICAL SOCIETY: DR. DONALD MACALISTER ON THE POISONS AND PHARMACY BILL.

IT might have been safely anticipated that there would be one subject the claims of which for discussion would be paramount in the speeches at the annual dinner of the Pharmaceutical Society, held in the Whitehall Rooms of the Hôtel Métropole on Tuesday last, May 15th. We refer to the acceptance by the House of Lords on May 11th of Lord Ebury's amendment to the Poisons and Pharmacy Bill, which legalises the use of chemists' titles by limited liability trading companies. After the usual loyal toasts had been honoured the President of the society, Mr. Alderman R. A. Robinson, J.P., L.C.C., in giving from the chair the toast of "The Houses of Parliament," said that he was sure that the peers who voted for the amendment of Lord Ebury did not fully understand the import of it. (Our readers will find in a full report of the debate in question at p. 1441 of this issue of THE LANCET the wording of Lord Ebury's amendment.) The decision come to by the House of Lords, which permitted persons who had passed no examinations to act as chemists, pharmacists, and druggists, did not merely concern the use of these titles. Their lordships' action meant that in future a company of unqualified persons would not be obliged to make up medical prescriptions according to the British Pharmacopœia. Such a company need not keep strong poisons, in accordance with the poisons regulations which are incumbent upon registered chemists. The net result of the amendment was thus to take the trading companies out of the regulations which were framed for, and enforced upon, pharmaceutical chemists for the safety of the public and in the interest of public health. Mr. Robinson trusted that the matter would be put right either in the House of Lords, while there was still time, or in the House of Commons later. In proposing the toast of "The Pharmaceutical Society" Dr. MacAlister, the President of the General Medical Council, made an important speech upon a subject that must especially interest him. He remarked that, like the General Medical Council, the Pharmaceutical Society is charged with a double duty, that of the education and the registration of pharmaceutical chemists. Registration and its privileges was the reward offered by the legislature to those who, by long and careful education, have qualified themselves, and after strict examination have proved themselves worthy to receive it. Registration was a personal recognition of personal fitness, and the so-called privileges of registration are merely the acknowledgment by the State that skilled work should be intrusted only to skilled hands and heads. So long as these privileges are open to any citizen who is found fit to be qualified it was, he considered, a gross terminological inexactitude to speak of them as being the monopoly of a class. It would be unjust and dangerous to the public for the State to allow an unintentional and unforeseen defect of the law to frustrate its purpose. The State meant by the principle of registration to hold out inducements towards personal qualification; it imposed limitations on the baneful activity of the unqualified in order to secure a constant supply of persons willing and also thoroughly able to serve the public as pharmacists, as dentists, or as medical practitioners. An ingenious application, however, of the law of companies, originally enacted for financial purposes only, has in certain hands gone far to nullify the inducements offered by the State and to break down the limitations protecting properly qualified practice. The General Medical Council, he added, had for years sought to persuade the legislature to restore to the public the safeguards that were meant for its protection and he believed that Parliament must sooner or later be brought to see the evil which must arise from the actions of unqualified persons exempting themselves by incorporation in greater or less degree from the reasonable restrictions of legislation. It was incumbent on Parliament to find a remedy for the present state of affairs. The plea for a reform in the law was surely unanswerable, for the law now lays down that what is illegal for one person becomes legal when seven men join to do it in a company! Mr. Tweedy, the President of the Royal College of Surgeons of England, replying to the toast of "The Medical Profession," said that he hoped that the Pharmacy Bill when it came before the House of Commons, where it would be discussed upon its merits, would finally be successfully passed, and all the medical profession will agree with him in this sentiment. After a short programme of music the proceedings at a very interesting dinner terminated.

THE MEDICAL DEFENCE UNION.

WE have received a copy of the "Annual Report and Statement of Accounts for the year 1905 of the Medical Defence Union." This forms the twentieth report since the incorporation of the society and the members may be congratulated upon the attaining by the union of its majority. To mark this year the council decided to hold the annual general meeting at Birmingham, a wise conclusion which will be sure to give satisfaction to those members resident in the Midlands. The report once more proves the great value of such a society. No member of the medical profession, be he consultant or general practitioner, is secure from attack by ill-disposed individuals. In addition, such attacks are usually made by persons totally without means, the main object apparently being to attempt to levy blackmail. Mr. W. E. Hempson (solicitor to the union) draws especial attention to this point in his exceedingly able and interesting report. Speaking of such cases, he says: "It is always to me, even now, with the experience I have had in the light of the union's work, a mystery as to how on earth people of the class I have indicated are enabled to get actions undertaken for them. The grounds of action are more often than not of the flimsiest character possible, though in many instances the patient, in his ignorance only, believes he has a grievance. What surprises me is that he can get his action taken up for him by a legal adviser who is prepared to conduct the proceedings on the footing of 'no cure no pay,' but that it is possible is sufficiently demonstrated by the records which I have given." We can cordially recommend to our readers a perusal of this report. The numerous cases cited by Mr. Hempson or noted in the schedule of cases selected from the minute book will at once demonstrate the necessity which we have so frequently insisted on of every member of the medical profession joining one of the defence societies. The cases quoted, however, by no means represent the total amount of work done but only a proportion of such. Were the council to publish details of all cases dealt with by the executive the report would require to be extended beyond reasonable limits. The secretary (Dr. A. G. Bateman) daily gives verbal advice to members calling at the office The main object of the union is to aid the members speedily and efficiently and therefore the secretary and the solicitor are empowered to act when necessary without waiting for a meeting either of the council or of the executive committee, reporting, of course, to the meeting following such action. By this method no delay in active intervention on behalf of a member threatened with an action is caused, and by such prompt intervention many a case is crushed at its initiation which if delay had been permitted would have gained power and strength and necessitated heavy expenditure of both time and money. It is this speedy action which is of such immense advantage to members of the union. If a practitioner is not a member such specially skilled and prompt advice is most difficult to obtain and the costs mount up at an amazing pace, and, as we have above pointed out, owing to the social and pecuniary position of those bringing such actions such costs can rarely be refunded. During the year 1905 188 cases were referred to the solicitor, 65 of which related to the suppression of libels and slanders published of, or concerning, members of the union; 22 to the defence of members in actions threatened or prosecuted and in which damages were claimed for alleged malpraxis; 19 were associated with the prosecution of unqualified practitioners; and 82 were of a personal and miscellaneous character. Notwithstanding the heavy expenses thus incurred we are glad to see by the balance-sheet that the finances of the union are in a most satisfactory condition. The total number of members on the register amounted to 6575, 532 new members having been admitted during the year.

IS ASPARAGUS WHOLESOME?

ASPARAGUS is the precursor of the season of fresh vegetables and there is probably no other vegetable the flavour of which is so highly esteemed as is that of tender asparagus. Chemical analysis offers no explanation of its pleasant flavour but assigns to it a decidedly high nutritious value. Asparagus, however, furnishes one of those interesting examples of a food which, though containing more water in its composition than does milk, is nevertheless a solid substance. Thus the head of the asparagus contains slightly more than 93 per cent. of water, which is only 1 per cent. less than that contained in the lettuce but 5 per cent. more than is present in milk. The solid constituents, however, are particularly rich in nitrogenous substances which amount to 30 per cent. of the dried vegetable. Amongst these may be reckoned a purin body, to which has been ascribed the harmful influence of asparagus on some persons with a gouty tendency. When asparagus is consumed in large quantities the output of uric acid is very distinctly increased. The same effect is obtained after drinking copiously of beer which also contains purin bodies, although they are entirely absent in wines and, of course, in spirits. Sweetbread may be objectionable on similar grounds. There is no reason for thinking, however, that when asparagus is eaten in reasonable quantities it causes any undesirable disturbance of the bodily functions. On the contrary, it is very digestible and is easily tolerated, even by invalids. A certain amount of prejudice exists in regard to asparagus owing to one peculiar effect on metabolism, which is well known to every consumer of it. During digestion a very small quantity of volatile product containing sulphur is formed which has a particular odour. This body, known as methylmercaptan, originates during intestinal digestion, most probably from the peculiar principle, asparagine, and has no reference apparently to the function of the kidneys. There are no doubt examples of persons who exhibit an idiosyncrasy towards asparagus and develop unpleasant symptoms after eating it, just as there are people who are poisoned by mutton or strawberries, but on the whole there is nothing to be said on physiological grounds against moderate indulgence in this very popular vegetable food.

THE CLEARING OF THE AIR.

FROM an interesting communication by Mr. A. G. R. Foulerton and Dr. A. M. Kellas, published in another column, it would appear that electrical discharges of high potential and rapid frequency are without direct effect upon micro-organisms but that indirectly these discharges destroy germs owing to the action of chemical substances formed as the result of electrical action on the atmosphere through which the discharge takes place. Amongst the products formed in the air on the passage of the discharge are nitrous and nitric acids and probably ozone and peroxide of hydrogen, all of which are powerful germicides, but more particularly so at the moment of their formation. It is well known that substances which in the free condition are comparatively inert are intensely active in the nascent state. In view of these results there seems to be little doubt that the occurrence of a thunderstorm must exert a powerful purifying influence on the air, even to the total destruction of organisms. It is often stated that a thunderstorm does good because it clears the air, but so far this statement has not received explanation in such precise scientific terms. Further, it would be interesting to determine whether the production in the nascent state of nitrous acid, ozone, or peroxide of hydrogen has anything to do with the "turning" of milk or the "hardening" of beer which frequently happens during the progress of a thunderstorm. The treatment of disease, as, for example, lupus, by "high-frequency" discharges may after all owe its success to the formation of these germicidal substances in the intensely active condition known as the nascent state, in which case the employment of "high-frequency" discharges would be merely a reversion to the antiseptic method but probably with more intense effect.

THE PATHOGENY OF DIABETES.

IN THE LANCET of May 5th, p. 1229, we published a paper on the above subject read before the International Congress of Medicine at Lisbon by Dr. F. W. Pavy. The researches of Dr. Pavy into the causation of diabetes are well known and consequently any further communication from him on the subject merits most careful attention. Various theories as to the pathogeny of diabetes have been expressed by competent observers from time to time but even now no unanimity of opinion can be said to exist. The kidney, the liver, and the pancreas have in turn been considered the organ in which the disease originated but most authorities now point to the nervous system as playing the most important rôle in the production of glycosuria. The exact manner in which its action is brought to bear, however, appears to be doubtful. Dr. Pavy adduces some powerful arguments in favour of the vaso-motor system supplying the chylopoietic viscera being mainly involved. He points out that it is in connexion with the neuropathic disposition that diabetes is most frequently found to exist and the more sensitive and highly strung the nerve organisation the more intense is the form that the disease assumes. He further remarks that a cerebral influence over the vaso-motor state is what is suggested as constituting the link between the brain and diabetes. But little is known at present of the physiology of the vaso-motor system of nerves through which cerebro-spinal influence upon vessels is exerted. Certain parts of the grey matter of the brain appear to be in touch with vascular areas and it is suggested that the nerve filaments of the sympathetic system are not only connected with the spinal cord and medulla oblongata but with spots at the surface of the brain which stand in the position of cerebral vaso motor centres. Upon these grounds Dr. Pavy considers that a chain of connexion becomes established, rendering it possible for diabetes to constitute a disease belonging to the neurosis class, the difference in its case being the implication of a particular area belonging to the vaso motor system instead of structures connected with voluntary motion, sensation, and the mind. Morat and Dufour, from their researches, maintained that sugar formation is a function of the liver cells, under the control of certain undetermined excito-secretory nerves which they considered distinct from the vaso-motor nerves. It may well be suggested that this nervous influence may be liberated by certain toxins and the pancreas may also have an influence upon this function. Doubtless other investigations will be made to corroborate or otherwise Dr. Pavy's conclusions but until such are concluded the pathogeny of diabetes must still remain in doubt, although his researches must be taken as being amongst the most important and suggestive yet published.

A PATIENT'S COMPLAINTS AS EVIDENCE.

ONE of the very few exceptions allowed by a court of law to the rule which rigidly excludes hearsay testimony as valid evidence is that exclamations and statements made by an injured or sick person concerning the symptoms from which he suffers may be admitted as evidence, for it is by the aid of such information that the medical adviser arrives at his diagnosis and is able to decide upon a line of treatment. Recently in the Supreme Court of Michigan there was an unsuccessful attempt to enlarge the scope of this exception. The victim of a railway accident called in the medical man who was permanently retained as the expert witness of the defendant railway company; to him she detailed her symptoms, notably certain localised pain and tenderness were alleged by her. The court held that to admit these statements as evidence would be a breach of the rule which forbids the production of hearsay testimony. The court suggested that even if the statements of the patient were admitted the possibility of malingering would have to be discussed fully. Apart from this phase, however, the court decided that it was the design of the plaintiff to make the communications for the purpose of enhancing her claim and that fact made them inadmissible for the reason that they were not the natural expressions of present sufferings but voluntary statements for an ulterior purpose and hence they were not within the above exception to the hearsay rule.

ANTE-PARTUM OPHTHALMIA.

IN the *Ophthalmoscope* for April Mr. Sydney Stephenson and Dr. Rosa Ford have published an important paper on a condition supposed to be extremely rare but which they think occurs more frequently than is supposed—ante-partum ophthalmia. By ante-partum ophthalmia they mean an inflammation of the conjunctiva produced in utero by infection with a microbe (generally the gonococcus), the incubation period of which has elapsed completely or partially before birth. They have found recorded 37 cases, to which they add 17 cases observed by themselves. These include seven cases in which the symptoms developed within 24 hours of birth—a time which they take for the present purpose as the minimum incubation period. The majority of cases of ophthalmia neonatorum occur on the third day after birth, which shows the duration of the incubation period. The text-book statement that the incubation period varies from a few hours to two or three days probably is due to inclusion of cases of ante-partum infection. The gonococcus appears to gain entrance to the conjunctival sac through membranes that have been ruptured some time before birth. Of 28 cases in which the time of rupture is mentioned the interval before birth was not less than 24 hours in 12 cases. But in 16 cases the interval between rupture of the membranes and the discovery of the ophthalmia was less than 24 hours. To explain these cases slight lateral tears of the membranes or infection through uninjured membranes must be assumed. A local factor is indicated in seven of the cases by the fact that one eye alone was affected at birth. In most of the cases the labours were normal. In 15 of the cases the gonococcus was found, in two the pneumococcus, and in one the bacillus coli. Many of the cases were at birth in the early stage of ophthalmia, but in two cases the disease had apparently run its course, leaving a damaged or shrunken eyeball. Perhaps in gonorrhœal metritis or endometritis gonococci pass through the chorion during early pregnancy when its vascular connexion with the uterus is marked. The hypothesis remains that the fœtal circulation may be infected in consequence of general gonococcic infection of the mother. Mr. Stephenson and Dr. Ford suggest that many congenital affections, such as staphyloma, corneal opacities, microphthalmos, lacrymal abscess, and vulvo-vaginitis, may be due to intra-uterine infection.

THE CARE OF THE SPONGE.

ONE of the most agreeable and convenient adjuncts concerned in preserving personal cleanliness is the sponge. Considering the extraordinary capacity of the sponge for holding water and the frequency of its use it is obvious that enormous quantities of water must in the course of time pass through its innumerable cells. For example, if a sponge which absorbs, say, a pint of water is alternately soaked and squeezed out a dozen times during a bath the amount of water that has entered into, and passed out of, the sponge at a single sitting, so to speak, would be 12 pints, so that during a year at this rate no less than 500 gallons of water would have traversed its cells. This estimate is not an exaggerated one and probably the sponges of most cleanly disposed persons are made to deal with a larger quantity than this. However that may be, it is obvious that the sponge must arrest the impurities of a water just as does a good filter and sooner or later slimy matter accumulates, the quantity and quality of which depend upon the character of the water-supply. The use of soap would, as a rule, increase the slime owing to the formation of insoluble curds of lime soap. The number of organisms and the amount of impurity in the water may be quite insignificant in relatively small volumes of the water, but when the accumulation caught in a sponge represents some hundreds of gallons of water the sponge may obviously teem with potentialities for evil. The bacteriology of water slime is of the greatest interest since it is this slime found on all the sand filter-beds which removes dangerous entities and thus protects a community from water-borne disease. The unclean sponge contains a similar slime which must prove a very prolific breeding-ground for micro-organisms. A consideration of such facts emphasises the desirability of keeping the domestic sponge absolutely clean and all doubt as to the presence of seeds of disease should be removed by thoroughly disinfecting the sponge at regular intervals. There is no better disinfectant for the purpose than sunlight and the sponges, after having been washed thoroughly in strong washing soda solution and rinsed in a weak solution of hydrochloric acid and finally in pure water, should be squeezed and hung up to dry in the sun's rays. This process also renovates the sponge in a most satisfactory manner. Amongst artificial disinfectants a weak solution of formaldehyde, or sulphurous acid, would appear to be suitable.

THE TREATMENT OF INOPERABLE SARCOMA WITH THE MIXED TOXINS OF ERYSIPELAS AND THE BACILLUS PRODIGIOSUS.

Dr. W. B. Coley has contributed to the *American Journal of the Medical Sciences* for March an important paper in which he gives the late results of the treatment of inoperable sarcoma with the mixed toxins of erysipelas and of the bacillus prodigiosus. It may be remembered that in 1891 he first described the treatment of inoperable sarcoma with repeated injections of the streptococcus of erysipelas. This treatment was suggested by a case of very malignant round-celled sarcoma of the neck, which recurred four times after operation. It finally so involved the deep tissues that operation was impossible. Soon after the last operation an attack of erysipelas occurred, which was followed by a relapse. The tumour disappeared and the patient was well seven years later. In a case of inoperable recurrent spindle-celled sarcoma of the tonsil and cervical glands Dr. Coley injected beneath the skin of the neck covering the tumour a culture of the streptococcus of erysipelas. A typical attack of erysipelas followed, the tumour broke down, and the outlying nodules disappeared. The patient recovered health but a hard fibrous mass remained in the tonsil which had lost its malignant character. He remained well for eight years and then succumbed to recurrence. Ten other cases (four cases of carcinoma and six of sarcoma) were treated in the same way but in six (including all the cases of carcinoma) repeated injections failed to produce erysipelas. In most of these slight improvement took place while repeated injections of the cultures were being given. In the four positive cases one patient remained well for eight years and then died from recurrence and another remained well for three and a half years and then died from metastases. The occurrence of two fatal cases caused Dr. Coley to abandon injections of the streptococcus of erysipelas for those of its toxins. To intensify their action he added the toxins of the bacillus prodigiosus. The value of his present paper lies in the fact that he is able to give his final results. He reports 36 cases in which the tumour disappeared under the treatment. These were as follows: round-celled sarcoma, 13; spindle-celled sarcoma, 16; mixed-celled sarcoma, two; epithelioma, one; chondro sarcoma, one; and three in which no microscopic examination was made. In ten of these cases the patients were well more than ten years later at the time of the report. In 26 cases the patients were well at periods varying from three to 13 years after treatment. In five cases fatal recurrence took place after the patient had remained well for periods varying from six months to three and a quarter years. These results would be remarkable in cases of primary operable sarcoma. But here the patients were beyond hope from operation. In carcinoma Dr. Coley finds that the toxins have a marked inhibitory action but that this is rarely curative. He has collected 60 cases of malignant disease treated by other surgeons with complete or partial success; 27 of the patients were alive and well at periods varying from three to 12 years after the treatment. These results certainly are remarkable but we think that it is a pity that Dr. Coley neglects to state what proportion the successful cases form of the total cases treated. However, he appears to justify his claim that this treatment should be a routine after all primary operations for sarcoma and carcinoma. As to the question of using the toxins before amputating in sarcoma of the extremities he has collected 12 cases, of which three are personal, in which this treatment rendered amputation unnecessary. In cases in which the sarcoma has become generalised by formation of metastases he was inclined to advise against the use of the toxins. But he has observed two successful cases and others have been reported, including one published by Mr. W. H. Battle. Dr. Coley claims that this treatment has one advantage over that by the x rays; he has seen rapid breaking down of the tumour under the latter followed by metastases, but he has never seen this result even in cases of the most rapid disappearance under the toxin treatment.

THE DECLINE OF THE MARRIAGE-RATE IN ENGLAND.

THE national and social importance of the recent marked and continuous decline in the English marriage-rate and birth-rate can scarcely be over-estimated. Two recent and valuable contributions to the *Journal of the Royal Statistical Society* conclusively demonstrated that the persistent decline in the birth-rate in England can only to a very slight extent be attributed to the decline in the marriage-rate. The recently issued annual report of the Registrar-General, dealing with the statistics for 1904, throws, however, new light upon the decline in the English marriage-rate during the past 30 years which is not devoid of public interest. The Registrar-General's annual reports, of which the one just issued is the sixty-seventh, have accustomed us to accept as the marriage-rate the number of persons married during a year in each 1000 of the population at all ages. Calculated in this manner, the marriage-rate in England and Wales declined, with slight fluctuations, from 16·7 per 1000 in the three years 1870–72 to 15·2 per 1000 in 1904, signifying a decline of 9 per cent. in the rate of marriage. In consequence, however, of the decline in the birth-rate the age constitution of the English population has been materially altered. For instance, during the last census decade (1891–1901) the number of persons aged under 15 years, increased by but 3·67 per cent., whereas the increase of persons aged upwards of 15 years was equal to 16·74 per cent. Mindful of this fact, the Registrar-General in his last report gives the proportion of persons married to 1000 of the unmarried and widowed population aged upwards of 15 years among whom the marriages actually occur. Calculated in this manner, we are told that the marriage-rate declined from 57·2 per 1000 in the three years 1870–72 to 46·5 in 1904; this shows that the true decline in the marriage-rate of the unmarried and widowed aged over 15 years was 19 per cent. instead of 9 per cent., based on the crude rate calculated upon the entire population at all ages. Census returns show the result of this decline in the marriage-rate, for whereas in 1871 the proportion of the married in the English population aged upwards of 15 years was 54·0 per cent., the percentage of the married declined to 53·4 in 1881, to 51·9 in 1891, and to 51·5 in 1901. This decline in the marriage-rate, which was most marked during the ten years 1871–81, appears to have been very general throughout England and Wales; the only counties which showed an increased marriage-rate between 1871 and 1904 being the metropolitan portions of Middlesex and Surrey and Essex, mainly due to the migration of London residents to the suburban districts beyond the metropolitan area. The largest decline in the marriage-rate during this period was 29 per cent. in Lancashire, 28 per cent. in Staffordshire and in the East Riding of Yorkshire, and 26 per cent. in Worcestershire and in the West Riding of Yorkshire. Speaking generally, this decline of marriage was far more marked in the urban than in the rural counties. For instance, it was less than 5 per cent. in Hertfordshire, Wiltshire, Herefordshire, Pembrokeshire, and Montgomeryshire, and the rate was stationary in Anglesey. This decline has, moreover, affected the marriages of bachelors and widowers and of spinsters and widows, although to a varying extent. During the period under notice (1871–1904) the decline in the marriage-rate of bachelors (aged upwards of 15 years) declined 14·4 per cent., while the decline in the marriage-rate of widowers was no less than 42·2 per cent. Similarly, while the decline in the marriage-rate of spinsters in this period did not exceed 19·3 per cent. that of widows was equal to 40·8 per cent. The Registrar-General calls attention to the interesting fact that in spite of the recent marked decline in the rate of remarriage among widowers and widows their proportions in the male and female English population respectively show a decline. Of 1000 males over 15 years of age enumerated in England and Wales in 1871 57·3 were widowers, while the proportion had declined to 52·6 per 1000 at the last census in 1901; and of 1000 females of similar ages the number returned as widows had declined from 116·3 in 1871 to 108·2 in 1901. It may further be noted that this decline in the proportion of widowers and widows in the English population is confined to the age-period 15–35 years, the numbers of widowers and widows above the age of 35 years having relatively increased during the period under notice. It seems, therefore, probable that the declining marriage-rate of widowers and widows in recent years should not be entirely attributed to their decreasing tendency to remarriage but may be partly due to increased duration of life and to a consequent decrease in the proportion of persons widowed at the younger ages. The expectation of remarriage obviously decreases with the increased age of the widower and widow. Concurrently with the general decline in the marriage-rate it is satisfactory to note a marked decline in the proportion of marriages of minors, although of those married in 1904 in England and Wales 46 per 1000 of the husbands and 153 per 1000 of the wives were under the age of 21 years. Compared, however, with the proportions that prevailed 30 years ago, the number of bridegrooms and of brides under age showed respectively a decrease of 41·4 and 29·6 per cent. While the general decline in the English marriage-rate suggests grave doubts of social well-being, the decrease in the proportion of marriages of minors must be viewed with satisfaction.

A SUGGESTION TO MEDICAL OFFICERS OF HEALTH.

IN a letter published in THE LANCET of May 12th, p. 1348, Mr. S. Constable calls attention to the continual anxiety caused to many medical practitioners by the dirty and ignorant women whom they so often encounter in their midwifery practice playing the rôle of nurse. He makes the suggestion that medical officers of health should induce their parochial councils to get someone to give free simple lectures to these women on the essentials of monthly nursing. There can be no question but that some such scheme would be of the greatest benefit to the poor. Only too often the women have to intrust themselves after their confinements to the tender mercies of some kindly neighbour anxious to do what she can but with little knowledge or to some so-called nurse quite untrained who is only too often a grave source of danger to her patients. No doubt a very beneficial effect will be exercised upon these women by the spread of better training amongst the midwives of the country. When they see the amount of care taken by the latter they will realise the great importance to their patients of cleanliness and the use of antiseptics. In the meantime, something is being done by the councils to teach the elementary facts of sick nursing in their schools, and some authorities at any rate have already at hand possible teachers and lecturers in the persons of the women inspectors of midwives. District nurses, too, in rural districts might well be called upon to spend some of their time in training the women who practise as nurses in their neighbourhoods. No doubt in time we shall see marked improvement in this respect and indirectly we may expect much good to result both in this and in other forms of nursing amongst the poor from the operation of the Midwives Act.

THE SERUM TREATMENT OF DYSENTERY.

AT a meeting of the Académie de Médecine of Paris on Feb. 20th Professor C. Dopter and M. L. Vaillard communicated an important paper on the Serum Treatment of Dysentery. They pointed out that dysentery was not the name of a disease but of a number of diseases, of which two principal forms—bacillary and amœbic—are recognised. It is only with the bacillary or epidemic form of the disease that their communication deals. They have previously proved by experiments[1] the specificity of the bacillus of dysentery, confirming the work of Chantemesse and Widal, Kruse and Flexner, and the Japanese bacteriologist Shiga. The subcutaneous inoculation of the dog or the rabbit with the bacillus produces typical and fatal dysentery. In these animals, as in man, the infection becomes localised in the intestinal mucosa and its lymphatic glands. The toxin of the bacillus produces the same effects, local and general, as the organism itself. When injected subcutaneously it shows an elective affinity for the intestinal mucosa, especially that of the large intestine, and produces the characteristic lesions of dysentery. The toxin has also an action on the nervous system which is shown by paralyses and terminal hypothermia. Shiga was the first to produce an antidysenteric serum. He immunised animals against dysentery and showed that their serum could prevent and cure experimental infection of the mouse and the guinea-pig. In man his serum reduced the mortality of the disease by more than two-thirds and almost immediately relieved the symptoms. In Germany Kruse prepared a similar serum but his results were not so good. Both Shiga and Kruse used cultures of the bacillus, living or dead, to immunise animals. They ignored the existence of a soluble toxin. The serum thus prepared possessed bactericidal but not perceptible antitoxic properties. In 1903 Charles Todd showed that the bacillus of dysentery secretes toxin, the repeated injection of which into the horse gives to its serum antitoxic properties.[2] In 1904 at Moscow Rosenthal immunised horses by means of living cultures and the soluble toxin and obtained a bactericidal and antitoxic serum, the use of which reduced the mortality of the disease from one varying between 12 and 17·5 to 4·5 per cent. At the Institut Pasteur since 1903 Dopter and Vaillard have immunised horses by the weekly and alternate inoculation of increasing doses of the living bacilli and the soluble toxin. The injections are first given subcutaneously and then intravenously. The serum of these horses has immunising properties against both the bacillus and its toxin. Subcutaneous injection of from 0·05 to 0 25 of a cubic centimetre at the time of experimental infection with a fatal dose, or several days beforehand, protects rabbits. The immunity lasts from eight to ten days; then it rapidly disappears From one to two cubic centimetres of the serum injected 24 hours after infection insures recovery. But when the injection is delayed 48 hours recovery is doubtful; by intravenous injection better results are then obtained. In man similar results were observed. Of 96 patients suffering from dysentery and treated by subcutaneous injection of the serum, many of whom had the disease in a severe form (from 30 to 288 stools daily), only one died. In the milder cases (from 15 to 30 stools daily) an injection of 20 cubic centimetres of the serum during the first five days immediately relieved the symptoms and proved curative in two or three days. The improvement was not so sudden or so great when the dysentery had lasted longer—from eight to 15 days. However, it was definite; blood no longer exuded from the intestine but the colic persisted, and the stools, though diminished in number, still remained frequent (from eight to 15 in the 24 hours). If another injection was given on the next day, and perhaps still another on the day following, recovery rapidly took place (in from three to five days). In the severe cases the action of the serum was even more marked. In cases treated early an injection of 20 or, better, of 30 cubic centimetres brought about recovery in three or four days. Sometimes a second injection on the following day was necessary and even a third or fourth injection was sometimes required. In very severe cases the dose was increased to from 40 to 60 cubic centimetres and in certain cases even to 80, 90, and 100 cubic centimetres. If the improvement was not thought sufficient the injections were repeated on the following days in increasing doses In one case they were given for 17 days and in all 1080 cubic centimetres were injected. Even in the largest doses the serum is innocuous.

ST. BARTHOLOMEW'S HOSPITAL VIEW DAY.

VIEW DAY at St. Bartholomew's Hospital was held on May 9th and the day was one of special interest in that the new buildings of the out-patient and special department block were far enough advanced for inspection. The evening entertainment was devoted to a very charming programme of ancient dances and music presented by Miss Nellie Chaplin. Every dance was introduced with a short description by Mr. F. Cunningham Woods. The primitive dance was probably always accompanied by words or perhaps we should say that the primitive song was accompanied by dancing. The vocal dance has now, however, almost disappeared, the chief survival being the solemn ceremony which is sung and danced before the high altar at Seville on the feasts of the Assumption and of Corpus Christi. Other survivals are to be found in children's singing games, a number of which have been collected by Miss Gomme. The Elizabethan ballet or Fa La is still in high favour with madrigal societies as a musical composition but it is never danced, two well-known instances being Morley's "Sing We and Chaunt It" and "Now is the Month of Maying." Miss Chaplin's entertainment did not contain an example of the Elizabethan ballet but the programme included, amongst others, examples of the pavane, the galliard, the chaconne, the passepied, the saraband, the gavotte, and the minuet, besides an Irish jig. The whole entertainment was thoroughly artistic and it is satisfactory to state that the fund for the pathological block in aid of which the entertainment was organised benefited by the sum of over 120 guineas.

A NEW METHOD OF DRESSING WOUNDS BY MEANS OF BENZOL.

M. E. Crouzel, in the *Répertoire de Pharmacie* of March 10th, p. 101, suggests a new method of dressing wounds by means of benzol. In his opinion the problem of maintaining a wound in an aseptic condition has hitherto been attacked along the wrong lines. His method is based upon the removal of pus which is of a fatty nature and serves to fix the other products of suppuration and set up complications by the accumulation of the various products

---

stitut Pasteur, July, 1903.

r, Dec. 5th, 1903, p 1456.

of decomposition and excretion on the surface of the wound. Pure benzol is selected as a suitable solvent as it is non-toxic while it possesses well-marked antiseptic properties. It is one of the best solvents of fat and when applied to a wound by means of a sponge of cotton-wool or gauze it readily removes all morbid products, including pus, epithelial scales, fleshy débris, and blood. At the same time, owing to the rapidity with which it evaporates, it promotes a pleasant sense of coolness on the parts to which it is applied. The characteristic odour of benzol may be masked by the addition of 2 or 3 per cent. of nitrobenzene or guaiacol. M. Crouzel suggests that the employment of benzol in surgical practice might be extended to the outward application of many medicinal substances, including camphor, quinine, morphine, strychnine, iodine, sulphur, and phosphorus. A solution of paraffin or guttapercha in benzol affords an impermeable dressing for wounds of wide applicability. For some purposes benzol might with advantage be dissolved in alcohol or in ether. As an anæsthetic application to painful wounds and to abscesses requiring incision a solution of menthol in benzol is efficacious. Instruments dipped in a 5 per cent. solution of vaseline in benzol do not rust. The cheapness of benzol is another point in its favour, especially in hospital practice, as it can be used in many cases in place of alcohol. But it is necessary to exercise care to protect the vapour from naked lights as benzol is highly inflammable.

THE CAMPBELL POPE MEMORIAL FUND.

An appeal to the medical profession is being made in order to render some tribute to the memory of the late Dr. Campbell Pope, who practised for many years in the neighbourhood of Shepherd's Bush and who commanded in so many directions the respect and affection of his medical *confrères*. The following circular has been issued by an influential committee and so clearly does it put the case that we do not attempt to add a word to its arguments.

The sudden death of the late Dr. Campbell Pope of Shepherd's Bush, on Jan. 2nd, came as a great shock to his many friends and elicited widespread sympathy with his widow and family of two sons and four daughters. For 30 years Dr. Pope had practised in Shepherd's Bush and besides endearing himself to a wide circle of patients and friends he had devoted no small share of his too busy life to public duties in connexion with his profession, serving as a vice-president, and formerly for some years as honorary secretary, of the Medical Defence Union, as chairman of the Kensington division of the British Medical Association, and as honorary secretary, vice president, and subsequently president of the West London Medico-Chirurgical Society. It was felt by some of Dr. Pope's intimate friends that his high personal character and life of public usefulness warrant some special tribute to his memory and when it became known that, owing to his heavy professional expenses and the education of his children, the widow and family had been left very inadequately provided for, his friends felt impelled to take steps to raise a memorial fund which might be devoted to supplementing the very limited resources of his family, and more especially to assist in completing the education of the children. In this connexion it may be mentioned that his oldest son is completing his curriculum of medical study at St. Mary's Hospital and that for examination fees and other expenses a substantial sum will be required before he can obtain his medical qualifications.

The names of the committee who have signed this circular note are as follows:—

Chairman: Dr. Frederick T. Roberts Treasurers: Dr. H. A. Caley, 24, Upper Berkeley-street, W.; Mr. C. R. B. Keetley, 56, Grosvenor-street, W.; and Mr. J. F. Long, London and County Bank, Hammersmith, W. Honorary Secretary: Mrs Brandon, "Oakbrook," Ravenscourt Park, W. Members: Mr. T. Gunton Alderton, Dr. A. G. Bateman, Mr. L. A. Bidwell, Sir William Bull, M P, Mr. A. St. Clair Buxton, Rev. W. Dunckley, Right Honourable Sir Walter Foster, M.P., Dr. W. S. A. Griffith, Sir Victor A. H. Horsley, Rev. S. K. Lockyear, Mr. A. W. Valsey, and Dr. James Wilson.

Donations or, if preferred, subscriptions over a term of years will be gratefully received by the honorary treasurers or by the honorary secretary. We shall announce in The Lancet the names of all donors.

THE SEISMOMETER IN ITALY.

Shortly after 5 A.M. on April 18th the first shocks of earthquake were felt in San Francisco, and at 2.25 P.M. of that day the Director of the Osservatorio Ximeniano in Florence (the Padre Alfani) announced that "the seismic apparatus had begun to register a perturbation due to a very violent earthquake. The first calculations indicate the shocks as about 9900 kilometres distant from the Observatory. The violence of these was such that many of our instruments have been put out of gear." Up to 6 P.M. the apparatus continued to register the passage of seismic waves; but at that hour (according to the Padre Alfani) it was still impossible to fix the scene of the telluric storm. A little later, at the office of the *Nazione* and other newspapers of Central Italy, arrived the first brief telegrams announcing the terrible calamity that had befallen San Francisco. The above coincidences are worth noting, as indicative of the advance achieved in seismometry since the first attempts of Babbage down to the instrument constructed some 20 years ago by Grey and Milne working on the lines of Ewing. Prior to these the Italians claim for Count Michele di Rossi of the observatory under Rocca di Papa in the Agro Romano the invention of a yet more delicate and efficient apparatus which registered the telluric tremors preceding the frightful earthquake at Casamicciola in the Bay of Naples in the July of 1883. On the strength of these indications it is well known Count Michele di Rossi issued his urgent warning to the hotel keepers at Casamicciola and other balneary resorts in the Island of Ischia; but—the season being then at its height and the "albergatori" reaping a richer harvest than usual—his message was ignored. Italian observatories, notably those at Florence and Padua, are by this time more perfectly equipped than that of Count Michele di Rossi, and, coöperating as they all are with increased energy and ampler subsidies, a still further advance may be expected from them worthy of the land of Galileo and Torricelli, of Galvani, Volta, and Marconi.

THE SOCIETY FOR RELIEF OF WIDOWS AND ORPHANS OF MEDICAL MEN.

We published last week a brief account of the annual meeting of this excellent society and we now take occasion to call the attention of our readers to its work and record. The society was founded in 1788, being the third of its kind to be founded in England, and is now one of the richest, if not the richest, in the country, the invested funds amounting to £98,810.

Any person duly registered under the Medical Act and resident within a radius of 20 miles from Charing Cross shall be qualified to be proposed for election as a member of the society. That the whole of any township or parish to which the 20 mile radius may reach shall be considered as entirely within the said radius.

The annual subscription is two guineas, payable either in one sum or in two half-yearly amounts of one guinea each. After paying for 25 years members become life members and are exempted from further contributions.

Every member whose age at the time of his election shall not exceed 30 years may become a life member upon payment of the sum of 20 guineas; if his age shall exceed 30 and shall not exceed 40 years, upon payment of the sum of 25 guineas; and if his age shall exceed 40 years, upon payment of the sum of 30 guineas; provided that such payment be made within three months from the date of his election.

Relief is granted only to the widows and orphans of deceased members. The advantages of the society cannot be too strongly or constantly urged upon the members of the medical profession, for at each quarterly court of directors relief has to be refused to many applicants simply owing to the fact that their husbands had not been members of the society. Some remarkable instances may here be quoted showing the advantages derived by the widows and orphans of deceased members. One widow, whose husband had paid £18 18*s.* in subscriptions, received in grants for herself and family the sum of £2272; another received £1654; three widows, whose deaths were reported at the last quarterly court, received an average of £700 each. At the present time a widow is in receipt of a grant of £125 per annum for herself and five children. The above are could be quoted. Full particulars of the society and proposal forms for membership can be obtained on application to the secretary at the offices of the society, 11, Chandos-street, Cavendish-square, London, W.

A PROVINCIAL sessional meeting of the Royal Sanitary Institute will be held at the municipal council chamber, Telverton-road, Bournemouth, on Saturday, May 26th, at 11 A.M., when a discussion will take place on sanitary administration in a health resort. The discussion will be opened by Mr. P. W. G. Nunn, medical officer of health of Bournemouth, from whom tickets for admission to the meeting may be had.

THE *London Gazette* officially announces that Lieutenant-Colonel Havelock H. R. Charles, I.M.S. (Bengal), surgeon of the staff of the Prince of Wales during the visit of their Royal Highnesses the Prince and Princess of Wales to India, has been made a Knight Commander of the Royal Victorian Order. Fleet Surgeon Robert Hill, R.N., of H.M.S. *Renown*, has been made a Member of the Fourth Class of the same Order.

BY permission of Mrs. William E Scott a drawing-room meeting will be held to-day, Friday, May 18th, at 3 P.M., at 11, Kensington-court, London, W., in aid of the Infants' Hospital. Mr. Benjamin Broadbent (mayor of Huddersfield) will preside. Mr. J. S. Fletcher, M.P., and Dr. C. W. Saleeby are expected to speak.

IN accordance with the Medical Act (1886) Amendment Act of 1905 the province of Nova Scotia has been recognised as affording under local legislature proper privileges to registered medical practitioners. The province has therefore been declared by the King in Council to be one to which the second part of the Medical Act (1886) now applies.

THE Association of British Postal Medical Officers will hold its annual banquet in the Whitehall Rooms, Hôtel Métropole, London, upon Wednesday, July 11th, at 7 for 7.30 P.M., "to meet the Right Hon. Sydney Buxton, M.P., His Majesty's Postmaster-General."

THE ceremony of laying the foundation-stone of the South London Institute for the Blind, Borough-road, Southwark, will take place on Thursday, May 24th, at 2.45 P.M. The stone will be laid by the Duke of Argyll.

THE Corporation of McGill University, Montreal, has unanimously resolved to confer the honorary degree of LL.D. on Dr. Donald MacAlister, President of the General Medical Council of the United Kingdom.

Baron Takaki, F.R.C.S., the late Director-General of the Medical Department of the Imperial Japanese Navy, has had conferred upon him by the University of Durham the degree of D.C.L.

THE annual meeting of the Children's Country Holidays Fund will be held at the Hotel Métropole, Whitehall-place, London, on Monday, May 21st, at 3 45 P.M.

CREMATION SOCIETY OF ENGLAND.—The report of the council of the Cremation Society of England for the year 1905 shows that during the 12 months under notice 95 cremations were carried out at Woking as compared with 138 in 1904. This considerable falling off is probably due in some measure to the increased number of crematoria in the country and the growing influence of Golder's Green. The council is contemplating greater activity in making the advantage emation more widely known by advertising in various The total number of cremations that have taken place at Woking to the end of 1905 is 2748.

SIXTY-SEVENTH ANNUAL REPORT (FOR 1904) OF THE REGISTRAR-GENERAL.

II.[1]

IN resuming consideration of this report we notice that considerable attention is devoted to the prevalance and fatality of tuberculosis and cancer—two diseases possessing in common these characters, first, that they are responsible for a large share of the total mortality in this country and, secondly, that they seriously impair the working capacity of the survivors from attack by these diseases respectively. The importance of tuberculosis as a factor in English mortality appears from the statement in the report that it accounts normally for at least 11 per cent. of the mortality from all causes. Out of every ten deaths from tuberculosis about seven are due to the pulmonary variety of that infection. Although, as compared with the average, pulmonary tuberculosis showed decreased fatality in the year 1904, yet even now it is responsible for between 1200 and 1300 deaths annually in each 1,000,000 of the population. This disease for the most part pursues a somewhat lingering course, the duration of illness in fatal cases being roughly estimated at about two years, and during a large part of this period the sufferer is seriously handicapped by increasing debility in his struggles to provide sustenance for his family and himself. Statistics show that, speaking generally, pulmonary tuberculosis is about half as fatal again to males as it is to females, the difference being more pronounced in the town than in the country. Disregarding counties of less than 100,000 inhabitants, we learn that among males pulmonary tuberculosis was least fatal in Monmouthshire, where the rate of mortality was 829 per 1,000,000, in Lincolnshire 881, and in Buckinghamshire 890 per 1,000,000. Among other counties the rate rose to 1618 in Carmarthenshire, 1622 in Northumberland, 1642 in Warwickshire, 1694 in Lancashire, and 1720 in Hampshire, whilst in London it amounted to 2106 per 1,000,000. Among females, whilst the rate did not exceed 750 per 1,000,000 in Oxfordshire, 780 in Worcestershire, and 783 in Staffordshire, it rose to 1166 in Durham, 1194 in Denbighshire, 1205 in Glamorganshire, 1316 in Northumberland, 1665 in Carmarthenshire, and 1819 in Carnarvonshire. It is noteworthy, however, that in the metropolis females do not resemble males in suffering exceptional fatality from this disease.

If the rates in the year 1904 be compared with the average in the preceding five years the following facts will be observed. 1. That in the country generally the mortality from pulmonary tuberculosis was below the average, except among males under the age of 15 years and among females at from 10 to 15 and at from 55 to 65 years. 2. That in the urban districts males under 20 years and from 55 to 65 years succumbed to this disease more readily than the average, the same being true of females at ages from 10 to 15 and from 45 to 65. 3. That in the rural districts males suffered more severely than the average at ages from 25 to 35 years, and from 45 to 65, and females more severely at ages from 5 to 10, from 15 to 20, from 25 to 35, and from 55 to 65 years. Except at the age from 15 to 35 in males and at the age from 10 to 35 in females, pulmonary tuberculosis appears to be more fatal in the town than in the country. The age of maximum fatality from this malady is now, and for several years past has been, as follows: in England and Wales generally and in the urban districts from 45 to 55 for men and from 35 to 45 for women; in the rural districts it is from 25 to 35 for both sexes.

From a table in the report we learn that of the eight European countries which furnish returns for publication in the Registrar-General's reports, in all except Italy the average mortality from pulmonary tuberculosis exceeded that of England and Wales. In Ireland the mortality was excessive and in Scotland it was higher than it should be. In New Zealand and in all the States of the Australian Commonwealth, except Victoria, it was considerably below the English rate. The death-rate in the Austrian empire, in Servia, and in Ireland is abnormally high and shows no tendency to decrease. On the other hand, in England, Wales, and Scotland and in five European countries—viz., Germany, the Netherlands, Belgium, Norway, and Italy—a diminution in the death-rate from pulmonary tuberculosis has taken place in recent years.

---

[1] Previous notices of this report will be found in THE LANCET of April 21st (p 1120) and May 5th (p 1254), 1906.

Although among adults pulmonary tuberculosis is the most frequent form of this infection, the report shows that among children tuberculous meningitis and tuberculous peritonitis are the forms that destroy the largest proportion of lives. The mortality from tuberculous meningitis appears to be decreasing; nevertheless, the disease destroys annually 125 boys and 104 girls in every 100,000 living of each sex at ages *under five years, a large proportion of these deaths* occurring within the first year of life. Tuberculous peritonitis is another member of this group which accounts for a large proportion of the mortality among young children, more than three-quarters of the deaths from this disease occurring in children of less than five years old. It is difficult to determine the actual mortality from this condition, partly because of want of uniformity in phraseology and partly because of exceptional difficulty of diagnosis in cases where, as is generally the case, necropsies are unobtainable. The indefinite and very objectionable term tabes mesenterica is still used by many practitioners to denote the present disease, although Dr. Tatham has ascertained that the use of this term has been long since abandoned by the medical staffs of the principal London hospitals. The mortality from tuberculous peritonitis is about the same as that from tuberculous meningitis; the former disease is, however, more destructive than the latter in the earlier months of life.

Unfortunately, no reduction can as yet be recorded in the steadily increasing fatality of cancer which has characterised the returns for many years past, the one hopeful sign at present discernible being that in the year 1904 there was no acceleration of the rate of increase of cancer mortality as compared with the average in recent previous years. The deaths from malignant disease in the year under notice were nearly 30,000 in number and exceeded the average number in the previous ten years corrected for increase of population. Among males the increase was equal to 13 per cent., against 6 per cent. among females. An idea of the suffering entailed by the prevalence of this terrible disease may be gathered from the fact that in the four years 1901–04 more than 5 per cent. of the deaths from all causes have resulted from it. The report shows the mortality from cancer in that section of the population which is almost exclusively liable to that disease, the rate being given for men and women separately at ages above 35 years; the fatal cases at earlier ages are also recorded but these are relatively few in number. After due correction for differences in age constitution of the population cancer is found to be more fatal in the town than in the country, although in the absence of such correction the country districts would appear to be the greatest sufferers. In this connexion Dr. Tatham draws attention to the impracticability in many cases of distributing to their former places of residence the deaths of cancer patients occurring in urban hospitals; he further remarks on the fallacy of assuming that the residence of a patient immediately before death had been also the place of origin of the fatal disease. The mortality from cancer is considerably higher in women than in men, the rate being 2970 per 1,000,000 annually in the former sex and 2271 per 1,000,000 in the latter. In both sexes the increase of cancer fatality has been greatest at the more advanced ages; it is also greater in the urban than in the rural districts.

Among the limited number of foreign countries furnishing returns the average death-rate from cancer exceeded that of England and Wales in three only—Switzerland, the Netherlands, and Norway. In the German and Austrian empires, in Italy, and in Servia the mortality rates were below that of this country. This was also the case in Ireland, New Zealand, the Australian colonies, Ceylon, and *Jamaica*. In all these countries except Ceylon, Tasmania, and Jamaica the proportional mortality from cancer has shown in recent years a tendency to increase.

In dealing with infantile mortality Dr. Tatham remarks that the subject of infant life preservation has in recent years achieved in the public mind a degree of importance that had never previously been attained since the establishment of civil registration in this country. Nevertheless, the loss of life in infancy is still enormous. According to the report it appears that nearly half the children dying under one year perish within three months of their birth, whilst of survivors in the second year of life there die more than twice as many as in any one of the three succeeding years. As children grow older their mortality declines. In the year 1904 the mortality from all causes in infants under one year was equal to 145 per 1000 births. In both sexes infantile mortality was about one-third higher in the urban districts than in the rural.

As in previous years, so in 1904 the loss of life among infants is mainly due to diarrhœal diseases, wasting diseases, convulsions, and diseases of the respiratory system. With few exceptions those countries in which a high birth-rate prevails are conspicuous for a high rate of mortality among *infants; nevertheless, as in the* case of France, a high rate of infantile mortality is sometimes coincident with a low birth-rate. Taking as a criterion the mortality in England and Wales it appears from the report that in seven European countries and in Ceylon, Jamaica, and Chili the rate of infantile mortality ranged from 3 to 117 per cent. above the English rate. In Japan it was nearly equal to, while in New Zealand, in Australia, in Scotland, in Ireland, and in six other European countries it was from 1 to 47 per cent. below, the English rate.

ASYLUM REPORTS.

Inverness District Asylum (Report for the year 1905).—The average number daily resident at this institution during the year ending May, 1905, was 654. The admissions numbered 140 and the discharges 96, of whom 79 had recovered, giving the high rate of 56·4 per cent. of the admissions, as compared with 43·8 per cent. for the previous year. The average recovery-rate for the Royal and district asylums of Scotland was 33 per cent. for 1904. The deaths numbered 52, which gives the low rate of 7·9 per cent. of the average number resident. This asylum receives patients from various counties in the Highlands, such as Inverness, Ross and Cromarty, and Sutherland. The medical superintendent, Dr. Robert B. Campbell, observes that many cases, from the northern districts more especially, are *admitted* in a hopeless condition, having been kept at home too long. The isolated position of many of the parishes, no doubt, accounts partly for the delay referred to, but the same tendency to keep cases at home as long as possible is noticeable in Wales as compared with England, and probably connotes a marked trait in the Celtic character. Amongst the cases admitted we note six over 70 years of age, whilst one old woman was over 90. 72 of the 140 admissions were considered hopeful in respect of recovery. As regards *causation*, 31 per cent. of the admissions showed "marked hereditary predisposition" to insanity, a low proportion in comparison with many other asylums, particularly when the district from which this asylum draws its inmates is considered. Alcoholic excess accounted for only 4 per cent. of the admissions. Amongst the discharges were 15 unrecovered cases who were allowed out under the supervision of their relatives or other guardians. Such patients are freely discharged from this asylum, whereby overcrowding is avoided. Dr. Campbell finds the crofters *willing* to receive these cases. This, of course, is the Scotch system of boarding out which has proved so advantageous. Of the deaths, 19 per cent. were due to pulmonary tuberculosis. The reports of two visits made by the Commissioners in Lunacy during the year are appended to the asylum report and these testify to the good work which is being done by the institution.

THE NATIONAL HOSPITAL FOR PARALYSIS AND *EPILEPSY, QUEEN-SQUARE.*—A Male Nurses' Association has been formed in connexion with this hospital, the membership of which is confined to male nurses who have been fully trained at the hospital. Masseurs are also sent out by the association who in all circumstances work under the direction of a medical man.

VACCINATION GRANTS.—Mr. J. D. Staple, public vaccinator for the Ashley district of the Bristol union, has been awarded the Local Government Board grant for successful vaccination for the sixth consecutive time.—Mr. A. G. B. Lory, public vaccinator for the Chudleigh district of the Newton Abbot union, has been awarded for the third time in succession by the Local Government Board the special grant for successful vaccination.

TESTS OF CERTAIN OPEN DOMESTIC GRATES.

[THIS REPORT IS SUPPLIED BY THE COAL SMOKE ABATEMENT SOCIETY.]

THE two series of tests which had in former years been carried out by the Coal Smoke Abatement Society, the details of which were published in THE LANCET of May 10th, 1902 (p. 1342), and Feb. 20th, 1904 (p. 529), respectively, created such interest both in the trades concerned and amongst the public that the society was anxious to secure an opportunity to carry out further tests on a more extensive scale. In the autumn of 1905 this opportunity arose through the kind initiative of Sir Henry Tanner, chief architect to H.M. Government. The large block of buildings situated at the corner of Great George-street and Parliament-street, Westminster, in course of construction under his superintendence, suggested the possibility of a further series of tests being carried out and he placed himself in communication with the Coal Smoke Abatement Society. As a result a subcommittee of the society, consisting of Dr. H. A. Des Vœux and Mr. W. H. Atkin Berry, F.R.I.B.A., the latter nominated as a member of the society by the Royal Institute of British Architects, was appointed to act in conjunction with Sir Henry Tanner in conducting the tests, and at a meeting of these gentlemen held in July, 1905, the following rules for the tests were drawn up:—

Regulations and Conditions to be observed by Manufacturers and others submitting Open Grates for Testing at the New Public Offices, Westminster, under the Control of the Commissioners of His Majesty's Works and the Coal Smoke Abatement Society.

1. The tests are intended to take place in October next and the grates should be delivered *free* not later than the 9th of that month, and owners will be advised when they are to send workmen to fix them in the fireplace openings appropriated to their several grates. The owners shall bear the expense of fixing and removing the grates.

2. The grates are to have a fire width not exceeding 20 inches across the front. The tests will be made with ordinary bituminous coal. The cost of fuel together with all other expenses attending the tests will be defrayed by the Commissioners.

3. Separate tests under similar conditions to the foregoing will also be made of grates suitable for anthracite coal and also of gas fires

4. It is intended as far as may be practicable to conduct the whole of the tests at one time and on one floor, and in rooms of nearly equal dimensions.

5. No owners of grates, nor any representatives, will be permitted to attend the tests. Owners may make suggestions in regard to their own grates, but the examiners may use their discretion as to adopting such suggestions.

6 The points to be ascertained by these trials are (1) prevention of smoke; (2) heating power; (3) economy of fuel; and (4) suitability for office and household purposes

7. The report of the examiners must be accepted by the exhibitors; and the Commissioners and the Society, or either of them, shall be at liberty to publish the results at which they arrive.

8. Tests will be made only upon the foregoing terms and conditions, and submission for testing will be taken as acceptance of such terms and conditions by the owners of grates submitted.

H.M. Office of Works, Westminster, S.W., September, 1905.

Announcements of the proposed tests were forwarded, together with copies of the rules, to as many manufacturers of grates as were known to the Coal Smoke Abatement Society and invitations to manufacturers generally to submit grates for testing were issued by advertisement in trade and other journals. As a result, by the month of October, between 40 and 50 grates were submitted, and after preliminary inspection by Sir Henry Tanner and the members of the subcommittee, and the elimination of such as were judged unsuitable and of others which were practically duplicates of selected grates, 24 were chosen and afterwards fixed in the appointed rooms for testing.

Description of rooms.—The rooms were situated round an open square court at the south end of the new public buildings, all being on the mezzanine floor and averaging, as near as possible, 4000 cubic feet in size, thus affording favourable conditions for testing which would otherwise not easily be obtainable. The chimney flues were all of the same length and size—viz., 68 feet high and 11 inches in diameter. Each room had one window, which was kept closed, and one door, the latter being opened only for the purpose of the necessary ingress and egress in attending to, and watching, the grates. The doors and windows in all rooms were of the same size respectively. There was no furniture in the rooms, the walls were of brick left rough and unplastered, and the floors and ceilings were of rough concrete, no floor-boards being yet in position.

Dates of Tests.—The tests were conducted during the four days, Dec. 4th, 5th, 6th, and 7th, 1905.

Staff employed.—Mr. H. C. Burnand was chosen to superintend the staff and his duties were those of general supervisor—viz., to see that the fires were properly lighted and stoked, the temperatures correctly recorded, and the smoke charts properly filled in. Under him were eight assistants. Three (Smith, Fountain, and Andrews) attended to the weighing of the coal and wood, stoking the fires, and also recording the temperatures; and five (White, Bax, Moir, Dorrington, and Hudson) were appointed to register the smoke. Of these, four were stationed on the roof in separate shelters, each shelter being in clear view of the six chimneys which were allotted to each observer. The fifth assistant acted as relief when temporary release was required by one of the others.

Method of conducting the tests.—The grates were indicated only by distinctive numbers and the chimneys by distinctive letters of the alphabet painted on each flue pot. The names of the grates were unknown to the testers. The allotment of chimneys for observation by each of the smoke recorders was changed on each of the four days—the observers thus having a different set of chimneys every day. The fires were prepared first with a layer of chips, then of wood, and then of coal. The coal was weighed out and brought in carefully constructed trays, with two divisions, each division holding five pounds of coal. The fires were prepared each morning before 8 o'clock, at which hour they were lighted and were regulated throughout the day with the object of attaining and maintaining a temperature of 60° F. in the room or as near that as possible. The temperatures were recorded every half hour, one thermometer being placed in the corridor outside the rooms, and two in each of the rooms. Of the latter one was fixed at a distance of five feet in front of the fire and three feet above the floor and the other on the wall approximately 15 feet from the fire. The smoke emitted was registered according to the scale devised by the late Bryan Donkin and was carefully recorded on charts at regular intervals of five minutes throughout the hours of testing, a separate chart being used for each flue. At 4 P.M.—i.e., after eight hours—the fires were drawn and when cold the cinders were separated from the ashes and weighed, and the weight of cinders of each grate was recorded and was subtracted from the weight of coal placed on the fire. The wood supplied to each fire was also weighed and half its weight was added to the amount of coal, making a grand total of the fuel actually burned.

The following are descriptions of the grates tested, arranged in alphabetical order according to the name of the patentees or manufacturers, and they indicate for each grate respectively the amount of coal consumed less the amount of cinders (as explained above), the average temperature produced, and the average of smoke emitted. The descriptions are supplied by the manufacturers, but their inclusion in this report is not to be taken as implying confirmation by the examiners of the statements set forth in them. The results stated at the foot of each have been added by the examiners. The averages are taken for the whole period of four days of eight hours each, making 32 hours in all. It will be seen that the average of coal consumption varies from 19 to 41 lb. approximately; of temperature produced from 4° to 11° F., and of smoke emitted from 0·13 to 1·51.

Messrs Barnard, Bishop, and Barnard, Limited.—A slow combustion grate, with solid brick bottom sloping to the front. The fire basket is formed entirely of firebrick five inches deep at the bottom bar and seven inches at the top bar, continued the full height to flue opening. All the bricks are removeable from the front when necessary without disturbing the others. A rack blower is provided, reaching to within two inches of the top bar, thus making it possible to obtain a bright fire soon after the putting on of fresh coals. The bars project slightly, fitting into slides so as to be easily removed.

Average amount of coal burnt, minus cinders, plus half the wood, 25·13 lb.; average temperature produced, 4·8° F., average for smoke, 0·83.

Messrs Alex Boyd and Sons.—The "Cavendish" smokeless stove (Boyd's patent.)—This is claimed as a stove that will burn hard smokeless coal. The fuel basket is mounted so that it vibrates with a touch of the poker or of the foot, clearing itself of dust. The ashpit is inclosed to prevent dust escaping. A chimney is, of course, a necessity to carry away certain invisible products of combustion. A blower is used when first lighting and until the fire is really hot. This stove is intended for large halls or corridors rather than ordinary rooms. The necessity of having a flue pipe out in the room makes it rather unsightly for private use.

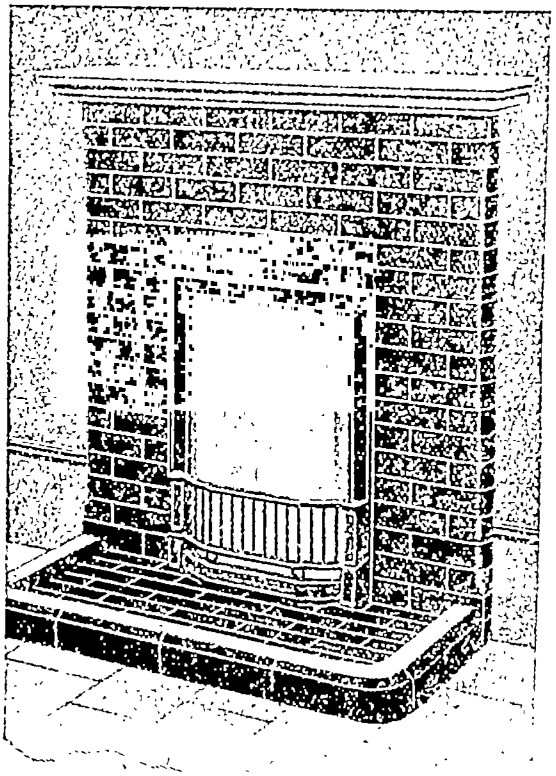
Coal, 33·07 lb. Temperature, 11·1° F. Smoke, 1·24.

Messrs. Bratt, Colbran, and Co.—The "Heaped Fire."—This not being a sunk fire, but in full view, and above the hearth level it is claimed that there is no danger from fire to hidden woodwork and that all through the day the hearth shall present a clean appearance. The fuel is heaped against the back brick. An economiser is provided to regulate the draught and when closed to make a slow-combustion stove. No underground channels for admission of air are necessary. The fire is constructed with a view to creating a draught suction and a steady incandescent fire.

Coal, 23·18 lb. Temperature, 6·8° F. Smoke, 0·87.

Messrs. Candy and Co., Limited.—The "Devon" fire (Fig. 1).—The Devon fire is constructed entirely of fireclay ware and is made for convenience in two pieces specially designed to radiate the heat most effectually towards the centre of the room; for this purpose the hearth is raised to the level of the fire. The lower portion of the fireplace has a solid bottom directly upon which the fire burns, there being no metal grid or air chamber beneath. It is claimed that the most perfect combustion is obtained by so placing the fire immediately on a solid block of fireclay and that with such an arrangement the question of ashes presents no difficulty whatever. The bottom may be made flat with detachable bars, as used in the present test, or may be hollow, in which case no bars are required. The illustration herewith shows a fire with flat bottom and detachable bars faced with a metal surround and moveable canopy, but these may be dispensed with and a simple brick arch substituted.

FIG. 1.



The "Devon" Fire.

Coal, 20·43 lb. Temperature, 7·4° F. Smoke, 0·79.

The Carron Company.—No. 391, Improved ventilating and smoke-consuming grate.—This grate is worked in a very simple manner which is effected by the use of flues constructed and filled with hot air on either side of the fire and superheated by close proximity with it. These flues, carried over the body of the grate, meet in the chimney immediately over the fire and at this point the superheated hot air is discharged and becomes the medium between the fire, the gases, and the smoke.

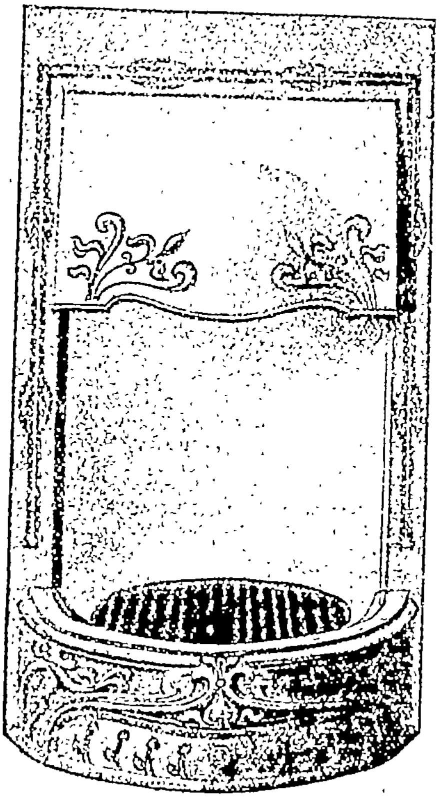
Coal, 34·68 lb. Temperature, 8·2° F. Smoke, 1·17.

Messrs. Chavasse and Kerr.—"Tropican" grate (patent).—This grate has firebrick backs with corrugated front, vertical construction, and a large radiating surface. The fire rests on a metal grating with a closed front and is raised about four inches above the hearth. When the front is closed air for combustion has access only to the top of the fire. To overcome stagnation a suction draught is introduced into the chimney through narrow passages formed in the firebrick. The air passing these passages is treated by coming in contact with the firebrick and is thus rarefied. The front heat generated in the fire is reserved for radiation, while a small quantity of heat behind which would otherwise be wasted, causes a steady and reliable draught from the room through the chimney.

Coal, 22·68 lb. Temperature, 6·6° F. Smoke, 0·97.

Messrs. J. and R. Corker, Limited.—The "Draw-well" grate (Fig. 3).—This grate is fitted with an adjustable canopy, semicircular and solid brick back, with solid brick back in front sloping inwards, the bottom forming a dish or basin with loose grate to lift out. There is a ventilating fret with pan attached. When the fire is out the bottom grate can be removed and the dust and ashes can then be carried away in the pan without causing them to fly about the room.

FIG. 2.



The "Draw-well" Grate.

Coal, 22·81 lb. Temperature, 8·3° F. Smoke, 1·02.

The Coalbrookdale Company, Limited.—The "Bostel" patent fireplace.—The "Bostel" patent fireplace is made so that the fire burns either sunk in the hearth or tilted up. The grate when tilted up induces a quick draught and when the fire has become a glowing mass the bars are lowered to the sunk position, bringing the fire well forward.

Coal, 41·43 lb. Temperature, 9° F. Smoke, 1·49.

Messrs. Doulton and Co., Limited.—Doulton's "Sunk Fire."—This fireplace is constructed with a fireclay well in which the fire burns on a removeable iron grid, this grid being raised to prevent the fire lying dead. At the back and sides of the well is a solid fireclay firebrick intended to radiate the heat downwards into the room. The fireclay well and back are intended to store the heat and to radiate it into the room.

Coal, 19·33 lb. Temperature, 7·4° F. Smoke, 1·14.

Downdraught Fireplace Company.—In the "Tiffin" interior a downdraught flue is carried up from the bottom of the fire on either side behind the usual firebrick cheeks. These flues are made to converge to a common centre immediately above the usual canopy and thence a single flue is carried round the oven or hot chamber, finally debouching behind the same into the chimney. On the underside of the oven where the converging flues meet a sliding soot door is fitted, reached for cleaning purposes by removing the adjustable canopy in the ordinary way. The downdraught flue is regulated by a damper fitted at the junction of the same with the chimney and this is actuated by a damper rod passing through the front of the stove.

Coal, 23·18 lb. Temperature, 7·3° F. Smoke, 1·0.

The Eagle Range and Gas Stove Company, Limited.—The "Premier Gold Medal Eagle Grate."—This grate was designed as an improvement on the old pattern "Eagle" grate. It is fitted with four sliding doors, two above the front bars and two on a level with the same. The object of the top sliding doors is to enable a bright fire to be obtained a few minutes after lighting or to revive a dull fire after having been left for some hours. The object of the bottom doors is to obtain slow combustion by drawing them in front of the bars and so exclude any air from the fire. Another special feature is that the front bars can be lowered so that the greatest amount of heat can be obtained from the hottest part of the fire. The top bars can also be entirely removed so that the grate may be used for burning logs, &c. The bricks are all made of a special shape with the intention that the heat shall be thrown into the room.

Coal, 25·18 lb. Temperature, 6·3° F. Smoke, 0·79.

The Falkirk Iron Company.—No. 503 "Interior" grate.—This "Interior" is an economic barless grate intended to effect complete combustion and economy of fuel. It is fitted with a hinged adjustable canopy but is easily removeable for access to chimney for sweeping. The bottom is concave in shape, of firebrick at back and cast-iron grating in front, and forms a well for the fire. The roll front is intended to prevent the fuel from falling on to the hearth. The back is composed of firebrick slabs fitted in cast-iron frames and is easily removed from the front when required without disturbing the grate.

Coal, 20·81 lb. Temperature, 6·6° F. Smoke, 1·13.

Messrs. Hattersley Brothers, Limited—The "Rage" grate.—This grate is constructed with five firebricks removeable from the front without unfixing the grate. The two sides, the back, the top, and the front are fitted in metal casing and cannot get out of position; there is also a strong metal bottom grating, draw-out ashpan, and barless front with moveable guard constructed with "hit and miss grid" to control the fire. The canopy swinging upon pivots is adjustable to several positions and is removeable for the purpose of sweeping the main flue.

Coal, 23·43 lb. Temperature, 6·5° F. Smoke, 1·14.

The London Warming and Ventilating Company, Limited.—The "Florence" patent grate with patent automatic shaking bars and combination canopy regulator.—This grate has a self-contained auxiliary flue controlled by a damper connected to the adjustable canopy. It is claimed that when the canopy is closed and the back flue is brought into use the smoke is drawn through a fire to a point where the heat is practically incandescent and is consumed to an appreciable extent. The automatic shaking bars consist of a number of separate bars loosely mounted on a square shaft and made abnormally deep in the body intended to heat the ascending air currents as the weight of coal varies in the different bars; the bars are intended to rock and clear the fire of ashes and dust, thus allowing a continuous current of air at a high temperature to pass through the fuel and cause it to burn brightly even in small quantities.

Coal, 27·13 lb. Temperature, 9·3° F. Smoke, 1·01.

Messrs. Longden and Co.—This grate has a firebrick deflector or knee-brick of a special section, calculated in relation to the bars of the fire and its consequently enlarged heating capacity. This brick by its reaction throws the heat of the fire forward and downward. The economiser below the fire forms a regulator for the draught.

Coal, 27·51 lb. Temperature, 8·8° F. Smoke, 0·92.

Messrs. O'Brien, Thomas, and Co.—The "Aureole" patent grate.—This grate is constructed with a firebox of loose firebricks encased in a metal frame with steel vertical spindle bars. The special feature of the grate is the patent fire regulator which is composed of a blower and a damper; the one part regulates the air passing into, through, and above the fire, and the other as it passes into the chimney, thus providing a means of regulating the combustion of the fuel. The canopy can be adjusted so that the space between the edge of the top bar and the bottom edge of the canopy is either four and a half inches or nine inches, and the regulator is adjustable so as to leave the opening into the flue from three-eighths of an inch when down to the full size of the flap when opened or at any intermediate point.

Coal, 27·43 lb. Temperature, 8·6° F. Smoke, 1·07.

Messrs. Alexander Ritchie and Co.—The "Castle Baynard" barless stove.—This stove is constructed without front bars. The fire is provided with a loose hanging plate at the back of the moveable canopy, the object of which is to allow a greater flue area at the top of the stove which may be partially reduced as desired without fear of the grate smoking. This plate forms two flues for the passage of smoke into the chimney with a view to assist the ventilation of the room without increasing the draught of the stove. When the canopy and plate are removed complete access to the chimney for fixing and sweeping purposes is provided. The scoop-shaped firebox projects towards the room with the firebrick lining hanging over the fire, the object sought being to secure the full value of heat in the room. It is claimed that this form of firebox causes the fuel to collect in the centre of the grate as it burns down.

Coal, 32·43 lb. Temperature, 8·9° F. Smoke, 1·04.

The Sinclair Iron Company, Limited.—The "Rosneath" open fire-grate.—This grate is constructed so that it shall wholly project into the apartment and radiate heat into the room from the side bricks as well as from the back brick. The top of the back brick is brought very close to the sloping cast-iron front of the grate, so that the orifice into the chimney is the whole width of the grate but very narrow back to front. The main communication between the fire-grate and the chimney is by means of a series of channels cut in the top of the back brick, and through these channels the gases escape into the nozzle and thence into the chimney.

Coal, 27·83 lb. Temperature, 5·6° F. Smoke, 0·85.

Messrs. Wilmer and Sons.—Bond's patent sunk fire-grate.—The sides and back of this stove are formed of six fireclay slabs standing upon a base brick, the back brick inclining forward with the object of deflecting the heat out into the room. These bricks are of extra height, being 36 inches from the base brick to the opening into the flue. The opening into the flue has a horizontal direction, the cold air passing through an iron plate at the highest point of the arch, with the object of causing the hot air to be diffused into the room. It is claimed that the fireclay base brick, upon which the loose bottom grating stands, becomes superheated and renders more complete combustion of the fuel. The bottom grating is constructed so that the ashes can be readily removed at any time.

Coal, 29·9 lb. Temperature, 7·9° F. Smoke, 1·06.

Messrs. George Wright, Limited.—The "Tandem" stove.—In this grate there are three flues behind the back which open into the ashpit at the bottom and the chimney at the top. There is a special gilled dead plate bottom, closed at the front, and a special controlled register door. The fire is lighted in the ordinary way with the usual smoke exit to the chimney. When the fire is well alight the register door is closed and it is claimed that the smoke is forced to descend the centre flue behind the stove-back to the ashpit, thence passing through the gills of the dead plate up the side flues behind the stove-back to the chimney.

Coal, 23·13 lb. Temperature, 6·2° F. Smoke, 1·2.

Messrs. Yates Haywood.—The "Bonfire" barless stove.—The fire of this stove is raised very little above the level of the hearth but sufficiently so to admit of the easy removal of the ashes when cleaning. is entirely lined with fire lumps which can be out without disturbing the stove. A "hit and miss" ventilator regulates the admission of air to the bottom grate. Through a space at the back of the fire lump superheated air passes from the ashpit and enters above the fire, this, and the form of the casing, which inclines forward, having for their object the securing of a more perfect combustion of gases from the fuel. Two other spaces having outlets at the top of the inclined brick perform a similar duty as the smoke leaves the stove. The side ducts or tubes on the right and left of the stove are fed by air drawn through the perforation at the bottom of the tiled slabs, with a view to causing it to become rarefied by contact with the sides of the stove and so to assist in securing a steady draught up the flue.

Coal, 26·63 lb. Temperature, 7·4° F. Smoke, 0·81.

Upon the result obtained the examiners selected the following grates for further test—viz., those of Messrs. Candy, Messrs. J. and R. Corker, and the London Warming and Ventilating Company (A.). The amount of coal consumed by these grates was found to be moderate in comparative proportion with temperature obtained; the fires were bright and clear and the smoke emitted bore favourable comparison with the results recorded for the other grates.

Arrangements were now made for testing the remaining 12 of the total number of grates selected from those submitted. They were fixed in 12 of the rooms used for the first set and the tests were conducted in a precisely similar manner. (See Table II.)

Date of tests.—The tests were carried out on Jan. 2nd, 3rd, 4th, and 5th, 1906.

The following descriptions (arranged in alphabetical order) and the results attained by the examiners followed the lines of the previous ones.

The "Arnott" grate.—The "Arnott" grate was invented more than half a century ago by Dr. Neil Arnott. Suppose the bottom bars—viz., the bars on which the fuel lies—to be removed from an ordinary grate and an open-topped cast-iron box, the top of which is the same size as the bottom of the grate, to be placed under the grate, the grate being raised half as high again as usual to give room for the box, which is 12 inches deep. Coal put in at the top of the grate will at first fall to the bottom of the box and if enough is put in there will be a continuous pile of coal from the bottom of the box to the top of the grate. This column of coal is lighted an inch or two from the top in the usual way with paper and a few sticks of wood and it is claimed that the upper few inches of fuel are rapidly blown into a state of active combustion as the bottom of the flue-pipe is very little above the top of the fuel, thereby causing a strong draught.

Coal, 31·13 lb. Temperature, 9·6° F. Smoke, 1·13.

Bell's patent basket fire-grate.—In this stove the brick entirely covers the fire and the shape of the brick insures, with reasonable care in setting, an absolutely solid backing. The hot-air chamber formed by the platform and ashpan is intended to promote combustion so as to leave no cinders. The platform is intended to form a safety guard and to shield the fire from a too rapid intake of air, also to preserve a clean hearth. The firebrick back is in one piece and being filled solid behind and wedge-stapled on to the metal front cannot shift when fractured by expansion and contraction.

Coal, 38 63 lb. Temperature, 9·7° F. Smoke, 1·28.

Chavasse's patent fire-grate.—This grate is composed of two vents, one frame, one fire-bottom, two fireclay cheeks, one fireclay back, one fireclay sloping top, or radiator. The object sought is that the air shall pass out of the room through the vents on each side of the grate and along a rebate or chamber in the back of the cheeks. The cheeks being hot from the fire the air becomes rarefied and passes up the rebates in the back of the fireclay back; at the top of the fireclay back the rarefied air passes out just over the fire and under the sloping top or radiator and the air at this point helps to consume the carbon.

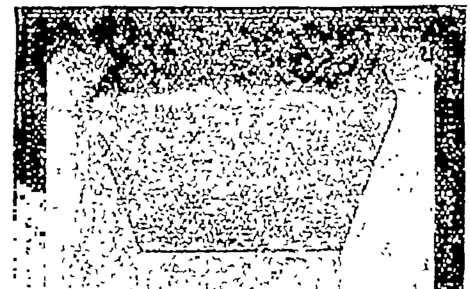
Coal, 21·43 lb. Temperature, 5·1° F. Smoke, 1·40.

The "Firth" grate.—The air is supplied principally from the back and sides, both inside and out, which are perforated and ribbed on the inside, having slotted openings in the bottom grate so as to allow the air to have free passage around the fire through the openings and up between the ribs. It is claimed for this grate that there is no rush of air from the front and that the moisture in the coal quietly ascends as steam, causing the light and heavy carburetted hydrogen gases to rise and to be met by from eight to ten times the volume of air which they require for the firing or explosive point, and burn with a bright flame, during which time the coal is coked, the impurities in the coal dropping to the bottom, none of them being driven into the atmosphere, and an incandescent fire being then formed.

Coal, 26·23 lb. Temperature, 3 1° F. Smoke, 0·66.

Messrs. Hendry and Pattisson.—A. D. O. Boyd's improved "Hygiastic" warm-air grate. (Fig. 3.)—These grates are supplied with fresh air from the outside with the object of circulating round the back of the grate and entering the room through a grating over the fire in a continuous stream, thus keeping the temperature even and ventilating the room by expelling the foul air. The cast-iron fronts are fitted with canopy or without, as preferred. The lumps are of fireclay and are sloped to assist radiation, and being built up of specially unbreakable joints it is claimed that they will not crack through unequal expansion or inter se heat. They are encased in a riveted steel back which is carried up and finished round the flue so as to simplify and lessen the cost of fixing. There are regulating valves for the smoke and air and a box ashpan under the fire for the purpose of keeping the hearth clean and economising fuel. The bars slope inwards with the intention of deflecting air into the fuel and preventing cinders or coal from dropping out.

FIG. 3.



D. O. Boyd's "Hygiastic" Grate.

Coal, 23·3 lb. Temperature, 7·2° F. Smoke, 0·13.

Messrs. Hendry and Pattisson.—B. No. 2, D. O. Boyd's improved "Non-warm Air grate."—The cast-iron fronts of this grate are fitted with canopy, or without as preferred. The lumps are of the best Stourbridge fireclay and are built up with extra unbreakable joints and secured to the front with wrought-iron straps. They are sloped with the object of assisting radiation and it is claimed that they will not crack through unequal expansion or intense heat. There is a regulating valve for the smoke and a box ashpan under the fire for the purpose of keeping the hearth clean and economising fuel when slow combustion is required. The bars slope inwards with the intention of deflecting air into the fuel and preventing cinders or coal from dropping out. The cost of fixing these grates is very small.

Coal, 33·18 lb. Temperature, 8 8° F. Smoke, 1·22.

The Nautilus Fire and Heating Company.—The "Nautilus" grate is a firebrick lined, slow combustion dog stove, and burns coal, coke, or wood. The products of combustion rise from the fire and pass off through the exit nozzles into the chimney. Heat is radiated directly from the open fire and indirectly from the whole exterior of the grate, particularly the hood. A register door for sweeping incloses the chimney immediately over the grate, with the object of obviating any waste of heat, and provision is made for regulating the draught from maximum to minimum by means of dampers on each side of the grate. The ashes fall through the grating into the concealed ashpan, thus allowing dust to fall upon the hearth and insuring greater safety.

Coal, 34·93 lb. Temperature, 6° F. Smoke, 1·22.

Messrs. Alexander Ritchie and Co.—"Castle Baynard" "level."—In this grate the front is formed of tiles which may be of any colour; the back is formed of fireclay; this hangs over the coals to cause the heat to be radiated into the room, especially on to the floor. The fuel is placed on a grating raised about four inches above the level of the floor with the intention of obviating the use of a raised hearth or an ashpit sunk below the floor level. The grating on which the coal lies permits of the ashes being cleared while the fire is burning; the ashes are received in a tray underneath and behind the moveable ashguard which also regulates the supply of air below the bars. The hearth, which is flush with the floor, becomes heated.

Coal, 18·63 lb. Temperature, 4·7° F. Smoke, 1·45.

Messrs. Smith and Wellstood.—An open fire-grate, with cast-iron front; the fire chamber is 18 inches wide and is lined at the sides and back with firebrick, with front bars and steel vertical bars An auxiliary flue is made through the lower portion of the back brick, passing up the back of this brick and entering the main flue behind the canopy. This flue is intended to draw the smoke from a newly stoked fire, partly through the incandescent fuel, there to be ignited and heat the back of the brick. A moveable canopy opens and closes this flue as required. When the canopy is open the flames pass up the front of the back brick as with an ordinary grate.

Coal, 26·43 lb. Temperature, 7·0° F. Smoke, 1·05.

The Teale Fireplace Company.—B. The Teale "Economiser Popular Type."—This grate has a firebrick back in four parts, readily replaced from the front, and inclosed in a double sheet steel casing forming an air chamber, air being drawn from outside and discharged from the grating above. The outlet for warm air is controlled by means of a louvre. In the case of the fireplace submitted for test, air had to be drawn from the room as it was not possible to get it direct from the outside. This fireplace is arranged with the object of preventing the smoke leaking into the air chamber.

Coal 20·93 lb. Temperature, 5·9° F. Smoke, 1·49.

Messrs. Wilson and Smith.—Patent "Peveril" stove.—The patent "Peveril" stove is constructed with a double canopy, one behind the other, and the back one is opened or closed by the wings at the back of the front canopy, pressing against the lower portion of the plate at the back. A plate divides the back flue into two parts and gives increased flue area. It is intended to prevent smoking and that any smoke missing the back flue shall be caught in the wide mouth of the front flue, and by this arrangement the combustion be regulated to any degree. There are no front bars.

Coal, 34·9 lb. Temperature, 6·3° F. Smoke, 1·11.

Messrs. Yates Haywood.—No. 1902, a heating and ventilating register stove.—This stove is constructed with a horizontally gilled back, which is inclosed with sheet iron, forming a warm-air chamber. It is entirely self contained, requiring no special fixing. Air is admitted to the chamber through the perforations, or fresh air from the outside is brought by a duct and enters at the base. It then is intended to pass backwards and forwards between the gills and thereby to become warmed and afterwards emitted through a "Hit and miss" ventilator into the room. Through a space at the back of the fire lump superheated air is intended to be drawn from underneath the bottom grate and to enter immediately over the fire and assist in the combustion of fuel and smoke. The back slopes forward over the fire. The grate is lined throughout with fire lumps which can be renewed from the front without disturbing the stove.

Coal, 23 9 lb. Temperature, 5·2° F. Smoke, 1·48.

Upon the results obtained the examiners selected three grates to be tested again, inasmuch, however, as the grate submitted by the London Warming and Ventilating Company and that sent by Messrs. Smith and Wellstood were found to be identical, the latter was not subjected to this test.

Dates of tests.—The tests were carried out on Jan. 30th and 31st and Feb. 1st and 5th. The results are set out in Table III.

TABLE III.—*Showing Results obtained on Re-testing Five Selected Grates.*

Names of firms (given in alphabetical order).	Amount of coal, less cinders, plus half wood, in pounds.	Ashes in pounds.	Stoking.	Temperatures (degrees Fahrenheit). I. Thermometer in passage.	II. Thermometer in room.	Difference between I. and II.	Radiation.	Smoke.

On the suggestion of Mr. A. O. Ackermann, M.I.C.E., the grates in the final series were submitted to the carbon dioxide test with the object of ascertaining their efficiency as coal-burning machines for producing heat. For this test the subcommittee secured the services of Dr. J. S. Owens, A.M.I.C.E., whose report is as follows:—

REPORT UPON THE THERMAL EFFICIENCY OF FIVE DOMESTIC FIRE-GRATES TESTED ON FEB. 5TH, 1906, AT THE REQUEST DR. DES VŒUX.

The following were the grates tested, which will be referred to by their respective letters:—

A.—Teale Fireplace Company	Room	11B.
B.—W. B. Clarke and Co.	,,	12A.
C.—D. O. Boyd's Improved "Hygiastic" Grate, by Hendry and Pattisson	,,	12B.
D.—Candy and Co.	,,	13B.
E.—London Warming and Ventilating Co. ...	,,	14C.

The accompanying table (Table IV.) exhibits the results of these tests which were continued for a period of eight hours simultaneously on each grate.

It will be seen that the grates showed in every case an extremely low efficiency when considered as a means of heating the air of a room. This efficiency is, as shown in Table IV., the percentage of the total heat or calorific value of the coal burnt which is actually utilised in warming the air passed through the room. The results show that less than 7 per cent. of the total heat of the coal is thus utilised. In the case of steam boilers from 70 to 75 per cent. of the calorific value of the coal is transferred to the water. Hence the efficiency of steam boilers is over ten times as great as domestic fire-grates.

Considering the two best grates, C and D, the quantity of heat given to the walls, chiefly by radiation, is very great, amounting to over 79 per cent. in C and 76 per cent. in D; but it must not be thought that this is all lost heat. It is well known that we feel warm in a room with warm walls in which the air is cold but we feel cold in a room with cold walls in which the air may be warm. This is largely because air is such a bad conductor of heat and because we are very sensitive to radiant heat.

Though a search has been made for similar data with which to compare the results of these tests, the only figures I have been able to obtain were kindly given me by Mr. Ackermann. He carried out some very complete tests of a hot water warming plant at a large London hospital, the results of which showed that 22 per cent. of the heat discharged from the radiators was utilised in warming the air of the room, while the remaining 78 per cent. was radiated into the walls and through the windows. Thus it will be seen that the percentage of heat taken by the walls was practically the same for the radiators and open fires, while the efficiency of the radiators in warming the air of the room was about three times as great as that of the open fires. If, however, we consider the efficiency of the hot water plant, taking into account all heat losses from the furnace to the radiators, the figures become more alike, being 8 per cent. of the heat of the fuel burnt for the hot water plant, as against 7 per cent. for the open fires. In the apparatus which Mr. Ackermann tested the distance from the source of heat to the radiators was abnormally great and consequently a very large quantity of heat was lost in transit.

In the case of the open fires the chimney losses, 14 to 16 per cent., are about twice as great as compared with the efficiency. In the case of the radiators, there are no chimney losses, the rooms being the equivalent of the *chimneys and rooms* together in the case of the open fires.

If for the open fires C and D we add the chimney losses to the heat given to the air of the room, we have, say, 21 per cent. and 23 per cent. as the combined efficiency, which compares very well with the 22 per cent. which Mr. Ackermann obtained in the case of radiators.

The details of most importance in Table IV.:—

No. 5, showing total ventilating effect.

No. 6, comparative ventilating effects per pound of coal burnt.

No. 13, showing the efficiency of grate.

No. 14, showing the percentage of heat lost or rather used in ventilating room.

No. 15, the percentage of heat used in warming walls of house. This heat is also doing useful work, keeping walls free from damp and radiating back into the room as pointed out above.

The meteorological conditions and the hygrometric conditions of the air during the test are shown in Tables V. and VI.

JOHN S. OWENS, M.D., A.M. Inst. C.E., &c.

As a final result of the whole of the tests before described the examiners find that of the grates submitted those of Messrs. J. and R. Corker, Messrs. Candy and Co., and Messrs. Hendry and Pattisson (Boyd's) are the best, showing practically equal results, and that the "Florence" (the London Warming and Ventilating Company) very nearly approximates to them.

It must be remembered that all these grates were worked with the object of obtaining their utmost capacity and not under the conditions obtaining in an ordinary room which would generally be more variable. The fires were not allowed to burn low, therefore the amount of smoke emitted in these tests was the minimum that can be expected.

It will be observed that the meteorological conditions during the period of testing were highly favourable.

THE
FIFTEENTH INTERNATIONAL CONGRESS OF MEDICINE.

Held at Lisbon, April 19th—April 26th, 1906.

THE SECTIONS.

ANATOMY.

Professor **NATHAN LOEWENTHAL** (Lausanne) contributed a paper upon—

A System of Histological, Cytological, and Embryological Nomenclature for the Entire Animal Kingdom.

The preparation of this paper which, as the title implies, is mainly concerned with microscopic anatomy, must have been a work of immense labour and research. The principal part of it is a vocabulary which fills 94 large pages and is arranged in double columns (one French and one German) on each page. More than 3000 various structures must therefore have their equivalent names given in the two languages. Some of the principal general headings into which the vocabulary is subdivided are as follows: Constituent parts of cells, epithelium of different kinds, glands, nerve tissue, muscular tissue, blood, lymph, connective tissue (including serous, mucous, and synovial membranes, fat, tendons, and nerve trunks), cartilage, bone, dental tissue, lympho-adenoid tissue, blood-vessels, lymphatic system, tegumentary system of animal types from the mammalia to the lamprey, and finally organs of special sense. The vocabulary proper is followed by about 24 pages of explanatory remarks, among which is inserted a page of diagrams illustrating various types of glands. In these remarks many suggestions are made with a view to secure uniformity of nomenclature. As an example of the unnecessary multiplicity of expressions it is pointed out that there are five synonyms for the striæ of muscular fibre. Under the heading of Blood the author says that in the most recent literature a distinction is made between leucocytes and lymphocytes but he doubts if the distinction is justifiable. He objects to the terms leucocytes or white corpuscles (*globules blancs*) because these cells are no whiter than many others and he suggests the designation lymphocytes as being preferable. Referring to the blood platelets (*plaquettes sanguines ou de Bizzozero, hématoblastes de Hayem*), he says that they are called thrombocytes in the most recent literature; they are supposed to have some influence on the coagulation of the blood; their origin and histological position are uncertain.

NEUROLOGY, PSYCHIATRY, AND CRIMINAL ANTHROPOLOGY.

Dr. **DAVID FERRIER** (London) read a paper upon

The Nature and Physiological Pathology of Tabes Dorsalis.

After giving a brief summary of the morbid appearances seen in tabes dorsalis he proceeded to consider various theories of the tabetic process, such as that it depended on primary interstitial necrosis, on posterior spinal meningitis, on syphilitic disease of the posterior lymphatic system of the spinal cord, and on general syphilosis of the meninges. After showing that valid objections could be raised to each of these theories he said that it seemed better to adopt the hypothesis of Thomas and Hauser that the fundamental lesion of tabes dorsalis was a dystrophy, similar to that produced by certain toxic agents, affecting the sensory protoneuron as a whole and leading to degeneration of its outlying parts, of which the central intramedullary prolongations were the most vulnerable. The essential factor in the degeneration of the intramedullary prolongations of the neuron seemed to be the absence of the neurilemma sheath in the intramedullary continuations of the posterior root fibres. The point where the fibres lost their neurilemma sheaths was, as has been emphasised by Orr and Rows, just after they have penetrated the pia mater. The hypothesis of a dystrophy of the sensory protoneuron as the fundamental lesion of tabes dorsalis rendered it easy to understand how not only the sensory protoneuron but other neurons in the sympathetic and elsewhere might be attacked in a similar manner. Dr. Ferrier then expressed his belief in the essential pathological identity of tabes dorsalis and general paralysis, both of them being, in his opinion, merely different aspects of the same polymorphic disease. Both were tabetic or wasting diseases, the dystrophy affecting mainly the sensory protoneuron in the one case and the psychomotor neuron in the other. Not infrequently the two affections were combined in the so-called tabo-paralysis. Clinically some of the most characteristic symptoms were common to both—notably the Argyll-Robertson pupil—and in both there was the same lymphocytosis of the cerebro-spinal fluid. The underlying etiological factors were the same—namely, antecedent syphilitic infection—and in both of them the development of the symptoms was on an average from seven to ten years after the date of the primary sore. It would, therefore, in his opinion, be advisable to recognise the identity of tabes dorsalis and general paralysis in medical terminology and to call them by the generic name tabes, classing them specifically as cerebral tabes (general paralysis), spinal tabes (tabes dorsalis, locomotor ataxy), and cerebro-spinal tabes (tabo-paralysis), according as the disease affected the brain, the spinal cord, or both conjointly. With regard to the physiological pathology of tabes dorsalis Dr. Ferrier confined himself to the consideration of one of its most characteristic features—namely, ataxy. In tabes dorsalis the motor neuron was intact, the electrical reactions of the muscles were normal, and their dynamic strength was not necessarily impaired. The paths of impulse from the cortical centres were free from degeneration and so also were the efferent tracts from the cerebellum. The lesion was therefore on the afferent or sensory side of the apparatus of movement and was manifested by loss of knee-jerk and by various forms of sensory perversion or impairment showing themselves in the skin, bones, joints, tendons, and muscles.

Dr. J. F. **SUTHERLAND**, deputy commissioner in lunacy for Scotland, read a paper upon

The Prophylaxis and Treatment of Criminal Recidivists.

He said that recidivism was the French-coined term most appropriate to express the persistent reiterated lapses of the same individual both among criminals charged with serious attacks on person and property and also among petty offenders whose delinquencies or misdemeanours were drunkenness, breaches of the peace, public disorder, prostitution, and vagrancy. The former were aggressive, noxious, anti-social, and to a slight extent industrious and productive; the latter, as a rule, were passive, idle, debauched, parasitic, and unproductive. The two types were quite distinct and there was little or no intermingling, for the recidivist engaging in the major crimes did not become a recidivist in the minor and petty offender class, and *vice versâ*. There were two principal causes of criminality. One of these was external to the recidivist—namely, environment and the economic conditions bringing it about and perpetuating it, whilst the other was internal and hereditary and required to be estimated by the psychological and the psycho-pathological method. Racial differences were not of much moment except in regard (1) to the drink habit so prevalent among the Celtic, Teutonic, and Slavonic peoples in Northern France, the United States of America, Northern Germany, Denmark, Sweden, Russia, Belgium, the Netherlands, and Great Britain and Ireland; and (2) to the habit of carrying lethal weapons practised by the Celtiberian peoples of Spain, Portugal, the Balkan States, Italy, and along the littoral of the Mediterranean. After a lengthy analysis of the statistics of crimes and petty offences in Scotland and England for 1903 Dr. Sutherland said that without exception recidivism of every description was in the main in every country a product of urban life. It was rarely met with in rural districts. Recidivists lived in the insanitary, overcrowded, and wretched abodes which formed the slums of towns and cities. With regard to the classification of criminals, Dr. Sutherland approved of the following classification put forward some years ago by Lombroso, Benedikt, Havelock Ellis, and others: 1. Criminals by passion. These were persons who acted on the spur of the moment and were known by their good lives and genuine remorse. 2. Occasional criminals. These were not naturally inclined to crime, but were weak and easily led. Bad heredity was prominent in this class. 3 Habitual criminals (recidivists). These were made up (*a*) of those who were weak and helpless mentally and physically and (*b*) of those who deliberately adopted a career of crime. The professional was the aristocrat among criminals and was often skilled and intelligent. 4. Instinctive criminals. To this class belonged the congenital or born criminal, the *uomo delinquente*, who was decreed by nature to be such. He was regarded by Lombroso as morally insane. His type was clearly of the degenerate stock. 5. Insane criminals. These were, in the opinion of the Italian school, an exaggeration of the instinctive criminals. On the subject of the punishment of crime, Dr. Sutherland expressed disapproval of solitary confinement and recommended the conversion of prisons into industrial reformatories with associated labour.

HYGIENE AND COLONIAL MEDICINE.

The Relations of the Mosquito to Yellow Fever.

ON Saturday morning, April 21st, the section on hygiene sat with the section on colonial medicine (Sections XIV. and XVII.). The chair was taken by Professor HUBERT BOYCE of Liverpool and the now well-known doctrine that yellow fever is propagated by mosquito bites was fully discussed. It was maintained that the yellow fever patient was only capable of infecting the stegomyia fasciata mosquito during the first few days at the beginning of the access of fever. Then it was argued that this mosquito only bit in the day-time or by artificial light. Professor Boyce said that for prophylactic purposes this did not much matter and the same precaution would apply both to the day and the night.

Dr. H. W. AUSTIN of the United States Marine Health Service said that yellow fever was a disease which came under his supervision and it was his duty to see that prophylactic measures were enforced. These precautions were all based on the theory that the mosquito was the cause of yellow fever. At New Orleans and elsewhere action had been taken by local authorities and he could not answer for the principles on which they proceeded. They might possibly differ with the central government of the United States. Where, however, the Federal authorities had interfered they invariably proceeded to screen the patients so that mosquitoes should not be infected by biting them. Then they endeavoured to destroy all the mosquitoes. They had been successful in a measure, notwithstanding that epidemics were in existence before any action was taken. Had they been warned sooner the results would have proved much more beneficent. Doubts might be entertained that the mosquito was the only means of spreading yellow fever, but that was the general, the true explanation, and facts demonstrated that with the destruction of the mosquito the epidemic ceased.

After this speech the discussion seemed to flag and might have ceased altogether but for the energetic intervention of Professor BOYCE. Speaking in French, he insisted on the importance of the whole question, particularly if they included the analogies and possible relationship between yellow fever and dengue and grippe or influenza. On this latter point he would ask Dr. Agramonte of Havana to give his opinion.

Responding, Dr. AGRAMONTE made a lengthy and interesting speech. There had been at Havana a remarkable epidemic of dengue. This disease had so many points in common with yellow fever that he thought that it had come to Havana from New Orleans, where the latter disease prevailed. In June last year the first recorded cases of undoubted dengue occurred in Havana. It spread more especially in the thickly-populated district occupied by foreigners, yet during a recent small epidemic of yellow fever there had been no cases in that quarter. Thus dengue did most mischief where yellow fever had done no harm. In the isolation hospital 70 cases of dengue were carefully studied from the first day until the end of the disease. During the first three days the symptoms in no wise differed from those of yellow fever. Albuminuria was believed to be a clear proof of yellow fever but it was also found in cases of dengue. It was accompanied with great pain in the limbs and back. The symptoms, however, were not perhaps quite so severe as in yellow fever. There were the frontal headache and the aching back, and the temperature was a little higher than was usual in yellow fever. No distinction between the two diseases occurred until the third day; then it would be found that there was no correlation between the pulse and the temperature. There would be a rather low pulse for a comparatively high temperature. Again, there was no eruption with yellow fever, though there might be suffusion of the skin.

Professor BOYCE, again urging a continuation of the discussion, pointed out that in Honduras albuminuria had been found with grippe or influenza and they could not easily distinguish these diseases from yellow fever. Therefore patients suffering from yellow fever had been treated as if they had only grippe or dengue and thus the mosquitoes were given time to bite them and to spread the disease.

Dr. CARLOS M. CORTEZO (Madrid) now gave a totally different turn to the discussion for he ventured to challenge the mosquito theory. He pointed out that in 1876 there had been an epidemic of yellow fever at Madrid. Some soldiers had returned from Cuba. These soldiers were immune; not a single case of fever occurred among them while they were in Madrid. They went and lived in poor quarters of the town, narrow, ill-ventilated streets. Natives of Madrid living in close proximity to these soldiers came to the hospital with fever and unfamiliar symptoms. No member of the hospital staff had ever seen a case of yellow fever but imagined that these might be cases of this disease judging from mere theoretical knowledge. Physicians were immediately sent for who in the colonies had acquired practical experience of the disease and they confirmed the diagnosis. Then it was that the belief that this disease could not travel so far inland was destroyed. Dr. Cortezo thought that the disease would travel wherever it found the necessary soil. The soldiers had brought sacks with them which had not been opened since they left Cuba. The Paris commission that investigated the matter found the state of the spleen, the liver, and other organs the same as in cases of yellow fever. The disease did not spread to other parts of Madrid but remained in those quarters where its development was favoured by insanitary conditions.

Before the discussion thus raised could be taken up a member present rose to urge that petrol should not be used alone but that a mixture, in equal parts, of creoline and petrol was much more effective in killing mosquitoes.

The CHAIRMAN rising pointed out that Dr. Cortezo had asked whether there were other sorts of mosquitoes capable of speading yellow fever and whether soiled linen could infect such mosquitoes? This was a practical question and must be answered. Others thought that the soil in the sewers could infect mosquitoes and that there was danger in dredging operations. He would ask Dr. Agramonte what was his opinion and whether there were other means than the mosquito by which the disease could be spread.

Dr. AGRAMONTE considered that at this late date it was not admissible that the mosquito theory could be challenged. This matter had been definitely settled by the experiments made by the American Commission. These experiments clearly proved that the disease could not be conveyed from one person to another except by the bite of the mosquito. 15 men—15 heroes—had consented to live in a small building where they were absolutely screened off from mosquitoes. In this building were placed the bedding and the clothing worn by yellow fever patients. The 15 men wore the dirty shirts of the yellow fever patients. They slept in beds befouled with the fæcal matter of yellow fever patients and rested their heads on pillows stained with the black vomit. In every way possible they exposed themselves to the contagion, yet not one of the 15 caught the fever. Nor must it be imagined that these men were immune. On the contrary, after the experiment three of the 15 were accidently bitten by mosquitoes and then they did contract the yellow fever. As for sanitation, at Havana the authorities cleared all filth out of the town and the greatest improvements were effected. Still, the yellow fever continued and it only stopped when they had killed the mosquitoes.

An American naval officer whose name was not given out here interposed saying that he was tempted to believe the mosquito theory but that the work done by the American Commission, however brilliant, could not be accepted as an absolute proof. He believed that there were cases of yellow fever in places where the mosquito did not exist.

Dr. **CORTEZO** begged leave to insist on his point. The heroic American experiments seemed to show that there was no danger in soiled linen. From the administrative point of view they must not allow such a conception to gain popular credence. It was, on the contrary, essential to prevent soiled linen being carried about from town to town and country to country. Perhaps mosquitoes could infect themselves by contact with such linen. Perhaps larvæ had been brought over in the dirty baggage and finding in the poorer quarters of Madrid congenial surroundings they developed and infected the Madrid population.

Dr. **ALBARRAN** (Cuba) thought it was dangerous to express any doubt as to the possibility of mischief arising from soiled linen. Commercial men would soon object to the precautions now taken to disinfect linen coming from ports where yellow fever prevailed.

Dr. **CORTEZO** added that he did not doubt the conclusions of the American Commission but those who were protected against the stegomyia were also protected against other varieties of mosquitoes. At Madrid no stegomyia had been found but there were yellow fever and plenty of other sorts of mosquitoes. These seemed to attack poor and dirty people especially. Then they had suffered from yellow fever not only in Madrid but in Andalusia and at Barcelona.

Dr. **FERDINAND CARO** (Madrid) also argued in the same sense. It seemed to be demonstrated by the actual state of science that mosquitoes were the sole cause but they might still have something to learn on the subject, and it would be very unwise to cease to take measures to prevent the importation of soiled linen from infected countries. In Cuba there were places where no yellow fever existed till after the arrival of Spanish soldiers.

Dr. **RAMOS** and Dr. **MAGALHAES**, both from Brazil, spoke and did not seem to attach much importance to the mosquito theory. They asked for information in regard to mosquitoes and paludal fever and what about the ships which had the fever, though there were no mosquitoes on board.

Dr. **AGRAMONTE** replied point by point, speaking this time in Spanish, as those who opposed his views seemed most familiar with that language. He maintained the mosquito theory and denied the possible importation of larvæ as they must have water to live. The mosquito could only infect itself with live blood. It bit only once and the person must be alive. It would not bite a dead body. The mosquitoes had great powers of resistance and were sometimes able to travel with a ship; then they went on shore when a ship reached a port. He thought that it was necessary to disinfect clothing and dirty linen for general purposes but not in so far as yellow fever is concerned.

Dr. **RICARDO JORGE**, President of the Section of Hygiene, said it was a Portuguese medical man who was the first to describe yellow fever which occurred during the siege of Lisbon. In Portugal they had numerous, continuous communications and traffic with South America. The predominating mosquito in Lisbon, Spain, and Italy is the specific mosquito, the stegomyia, so that it was necessary to take measures against the possibility of another invasion. Therefore passengers were watched for seven days. Though the period of incubation was said to be 13 days it was not practicable to continue to watch passengers for so long a time, but all their soiled clothes and linen were disinfected. This had been an established practice before the advent of the modern theory in regard to mosquitoes. Since 1893 no infected or suspected ship had entered Lisbon. In regard to Madrid he did not see how a mosquito could travel so far inland.

Dr. **KOPKE** replied that the eggs might be infected and they could travel any distance. The real question, and this should be experimentally studied, was whether the taint of yellow fever was hereditary among mosquitoes.

Dr. **CORTEZO** explained that in speaking a language with which he was not familiar he had used the word larvæ when he obviously meant eggs. He of course knew the former could not live without water. Perhaps they had in the hereditary and egg theory the explanation of the discrepancies that still exist in the theory of the infected living mosquito. This insect was not ubiquitous; it could not go everywhere, following soldiers from Cuba to Cadiz in a steamer and from Cadiz to Madrid in a railway carriage.

Dr. **AGRAMONTE** replied, admitting the possibility of this latter hypothesis. The egg had not been proved to be offensive or inoffensive. Perhaps the egg might bring forth the pathogenic mosquito and this might explain facts that seem to contradict the mosquito theory.

Thus the debate concluded and the egg supplied the link to bring the contending parties together. The tremendous clatter of voices, however, that broke forth the moment the President left the chair proved with what interest the discussion had been followed and that the somewhat large audience had been worked up to a considerable pitch of excitement.

In the afternoon Professor **RUBERT BOYCE** delivered a lecture on

The Prophylaxis of Yellow Fever,

in which he insisted on many of the points elucidated by the debate described above and the lantern views showed how the patients and the water-butts were screened against the approach of mosquitoes. Of course he insisted on immediate notification and isolation of cases. He then also showed how houses were to be fumigated and otherwise treated so as to kill all the mosquitoes lodged within. Further, he insisted that success was often only partial because the necessary measures were only partially applied. Still great progress had been achieved and thousands of lives had been saved.

Tuberculosis and Chalk and Lime Dust.

On Monday morning in the Section of Hygiene the discussions commenced at 10 o'clock.

Dr. **GASPAR FISAC** read a paper to show that lime and plaster workers were immune from pulmonary tuberculosis. Many provincial medical men had observed this fact. It would seem as if breathing the dust of lime and chalk acted as a preventive, for in the same districts other sections of the population suffered as usual from this disease.

Councillor Dr. G. **ENNES** thought the suggestion made was somewhat empirical. No theory had been advanced. Lime dust might have some action but plaster was quite neutral.

Dr. **LOEFFLER** inquired whether any experiments had been made with animals.

Dr. **FISAC** replied in the negative but said that he had made patients breathe a mixture of lime and plaster pulverised and with good results.

Mont Estoril as a Winter Station.

Dr. D. G. **DALGADO** then read a lengthy paper on the climate of Mont Estoril which is a popular health resort within half an hour's railway ride from Lisbon. It is advertised as the Portuguese Riviera and aims at being largely frequented by those who desire to escape from the rigour of northern winters. After criticising some writers who had not spoken favourably of the climate of Lisbon and its neighbourhood, he proceeded to explain the topographical position. Mont Estoril was in the same latitude as Palermo and 500 kilometres south of Nice. He would compare its climate with that of Catania, Nice, and Biarritz because official statistics existed in regard to those celebrated climatic resorts. He maintained that the climate of Mont Estoril was as uniform as that of Nice and more so than the climate of Biarritz. It lay directly under the influence of the Gulf Stream and in winter was from 1° to 3° C. warmer than its close neighbour Lisbon, the latter town not being so well sheltered and standing a little further inland, while Mont Estoril was immediately on the shores of the Atlantic. Cintra, which was 1775 feet above the sea, helped to shelter Mont Estoril from northerly winds and its average temperature was some four degrees Centigrade lower than that of Lisbon. In regard to humidity this was well within the desirable limit of 70 to 80 degrees of relative humidity. On the whole the winds were stronger in summer than in winter.

uring the winter there were no snow-capped mountains near hand and that was an advantage. The nearest snow was r away in the extreme north of Portugal and there Mont strelle had snow for six months of the year. Medically, e station of Mont Estoril was intermediate between e tonic and stimulating and the tonic-sedative. It would t as a stimulant in cases of debility following upon vers but was, perhaps, too stimulating for certain conditions heart disease. In cases of infantile wasting and of senile bility and in some forms of dyspepsia the climate of Mont storil has produced a tonic and a stimulating effect. As a dative and tonic combined it was useful, said Dr. Dalgado, most cases of asthma, insomnia, and nervous irritability. he equable temperature and comparative dryness were xtremely useful in chronic rheumatism and gout. It was, he aintained, an ideal place for rest. Some cases of consumpion would also be benefited by this climate but their dmission was not allowed. Going into the statistics of emperature, Dr. Dalgado said there had been observations ade at Lisbon for 46 years now and these showed hat during the three winter months, December, January, nd February, the mean temperature was 10 63° C. nd the diurnal fluctuations were for December 6·48°, for anuary 6·55°, and for February 6·11° C. According to he official figures given by Dr. Lalesque of Arcachon he mean temperature of Biarritz was 7·79° and of Nice ·91° C. The diurnal variations for the same three months ere 6·66°, 6 57°, and 10 79° at Biarritz; and 10·31°, 9 69°, nd 10·79° at Nice. For Catania the statistics available apply o only one year and they state that the mean temperature uring the three winter months was 10·08° C. and the diurnal luctuations were 4·05°, 6 05°, and 6·08° for the same three months. Therefore, these figures showed that the climate of Lisbon and Mont Estoril was better than that of Biarritz and Nice and nearly as good as that of Catania in Sicily. These observations also applied to the other seasons of the year; in no month were the fluctuations greater than at Biarritz and Nice. Indeed, the yearly fluctuation was only 11·42° C. at Lisbon, while it was 13·19° C. at Biarritz, 15·61° C. at Nice, and 20·08° C. at Catania. Therefore Lisbon was more equable than any of the other three places. The mean humidity for the three winter months was 79·1, 79·2, and 79·3 at Lisbon; 73 6, 75·7, and 73·3 at Biarritz; 74 7, 75·1, and 74·6 at Nice; and 70·7, 67·0, and 66·0 at Catania. According to Professor Jaccoud the ideal was between 70 and 80. Of course, Mont Estoril would show similar but somewhat better figures than its close neighbour Lisbon. Also, in regard to Mont Estoril it should be remarked that three out of the four winds were sea winds. The northerly winds were sea winds broken by the Cintra mountains and the hill of Mont Estoril itself. These might be described as attenuated sea winds. But the north-west, the west, and the south-west blew directly up on Mont Estoril from the broad expanse of the Atlantic.

Mr. G. JACKSON (Plymouth) asked a few questions as soon as Dr. Dalgado had terminated his paper. Before he could venture to recommend his patients to winter at Mont Estoril it would be necessary to know some details as to the drainage and general sanitation of the place. He had been told that the sewer outfall was exposed at low tide. Then he thought that there was not sufficient hotel accommodation. Also, if tuberculous patients were not admitted that was a serious obstacle and he wanted to know whether such restriction applied to the whole neighbourhood. It was just the sort of place to which to send early cases. Again, were the sewers ventilated and how? Finally, what about the water-supply? He had been told that it was good in one part of Mont Estoril and not in the other.

Dr. DALGADO replied that no place in Portugal was so well drained as Mont Estoril. In regard to ventilation, the hotels had ventilating shafts but whether they were intended for the ventilation of the soil-pipes or of the sewers was not stated. The fact that the whole place sloped towards the sea aided the drainage, said Dr. Dalgado, oblivious of the fact that steep gradients greatly complicate the ventilation problem. As for hotel accommodation, there were only two hotels at present, but there would be more as soon as the demand made itself felt. There had been an increase of accommodation equal to 15 per cent. last year and to 30 per cent. this year. In regard to tuberculous patients, it was illegal for persons suffering from that disease to enter a hotel and the hotel proprietor would be punished for receiving them. No country more early admitted the contagious nature of pulmonary tuberculosis. A house or villa where there had been a case might remain vacant for four or five years; no one would live there. Tuberculous patients must go to sanatoriums built expressly for them.

Dr. Loeffler's New Method of detecting Typhoid Bacilli.

On Tuesday morning, April 24th, the proceedings in the section of hygiene were opened by Dr. LOEFFLER who spoke about a new method of verifying the presence of the typhoid bacillus in liquid matter. These bacilli were rapidly destroyed by the colon and other bacilli that grew at the same time. If, however, they took a little peptonised beef-tea and phosphoric acid and added thereto some malachite green, the colon and other microbes would be killed but the typhoid bacilli would not be destroyed. Should fæcal or such substances be added the typhoid bacilli would be destroyed at 35° C. By adding gelatin, phosphoric acid, and malachite green the typhoid bacilli would multiply in about 10 or 12 hours. If then a small quantity was put into gelatin and care was taken to maintain a temperature of 24° C., the bacilli would grow in different directions forming colonies. Under a magnifier these strange colonies were readily seen. The method works easily and Professor Loeffler expressed the hope that it would be of practical service in the struggle against typhoid fever.

Professor Dr. UHHENBUTH (Greifswald) said a few words in German, to which Professor LOEFFLER replied that the bacilli in question all belonged to a great botanic family but some branches could grow and others could not in malachite green. If to this substance the bacillus coli was added its nature began to change. It would ferment and green would appear on the surface. If the typhoid germ was added no change took place. Therefore, with the aid of this solution they were able to distinguish between different members of the same family.

Miscellaneous Questions.

Dr. RAMIRO ARROYO (Béjar, Portugal) read a paper on the injury resulting from drinking soft waters. He described a locality in Portugal where the water drunk was almost like distilled water and explained that salts had to be added. The section generally agreed as to the injurious effect of waters that contained no salts, such as, for instance, melted snow.

Senhor MELLO DE MATTOS followed on the necessity of teaching hygiene in all the secondary schools and had a good deal to say on what he termed healthy thoughts or the hygiene of the mind.

Dr. OLIVEIRA LAZES (Lisbon) gave some figures taken from private practice to show that syphilis was a predisposing cause of tuberculosis. The effective control of prostitution was a means of checking the growth of tuberculosis. After a few remarks from different members the section adjourned.

The Vital Statistics of Portugal.

There was a good discussion with a numerous attendance at the last meeting of the section held on Wednesday morning (April 25th). First, the President of the Section, Dr. RICARDO JORGE, dealt with the vital statistics of Portugal. Taking the last four periods of five years each, terminating in 1904, the population of Portugal increased from the year 1886 to 1904 from 4,878,978 to 5,556,814 and the average death-rates decreased. They amounted for each of the four periods of five years to an annual average of 22·71, 21·20, 21·29, and 19·98 per 1000 of the population. The birth-rate, however, during the same five-year periods, fell from 33·41 to 30·96, 30·19, and then rose again during the last period of five years to a yearly average of 32·11 per 1000 of the population. The increase of the population was nevertheless due rather to the saving of life than to the augmentation of births. The sudden rise in the birth-rate was set down to the fact that Portugal was recovering from a period of severe financial depression.

This paper was followed by another demographical study by Professor SOBRAL CID of the Coimbra Faculty of Medicine on Infant Mortality in Portugal. It amounts to 137 per 1000 for infants under 12 months of age and it is less than in the other Latin countries, the figures being for Spain 191, for Italy 190, for France 168 and for Belgium 162. But the infant mortality amounts to 222 at Oporto and 189 at Lisbon. The infant mortality at Oporto is in excess of that of the French and Italian towns, excepting the town of Rouen, while that of Lisbon is above that of the European capitals with the exception of Rome and Madrid. Thus the low infant death-rate in Portugal is due to the predominance of the rural population.

Mr. ADOLPHE SMITH attempted to deduce a moral from the facts which had been submitted to the section. First he pointed out that the modern, more humane, and scientific methods of medical inspection and disinfection which had replaced the antique and cruel practice of maritime quarantines had in no wise affected the death-rate. On the contrary, there had been fewer, not more, epidemics. Secondly, the death-rates quoted had shown the indissoluble connexion between hygiene and political economy. When the national finances of Portugal were at an exceptionally low ebb the death-rate reached its highest point. The geographical distribution of a high infantile mortality showed that there was the greatest fatality where the pressure of economic necessity drove mothers from their infants' cradles to attend the machines in large mills and factories. The best sanitation was of little avail against the grip of starvation, and the two preceding Portuguese speakers had rendered a great service by supplying statistics that conclusively demonstrated the intimate connexion between economic pressure and the high general, and more especially the high infantile, rate of mortality.

These arguments were enthusiastically endorsed by the section and its PRESIDENT moved a special vote of thanks to the speakers.

Senhor FRIGUEIROS MARTEL, a civil engineer, submitted some tables on the comparative amount of food consumed in Lisbon and in Paris. These amounted in albumin to 105 407 grammes in Lisbon and to 107 630 in Paris per head per day, an advantage of 2·273 in favour of Paris. For fats or grease the figures were 48·47 grammes for Lisbon and 56·54 for Paris, again an advantage of 8 07 grammes for Paris. Finally, the amount of carbohydrates is 398·99 grammes at Lisbon and 400·10 at Paris, an advantage of only 1·11 for Paris. In Paris also there is a much larger consumption of alcohol, amounting to 9·5 cubic centimetres of pure alcohol per head per day, whilst at Lisbon it is only 1·5 cubic centimetres per head per day. The speaker insisted on the necessity of more abundant food for the manual workers. He was followed by Dr. MASIP who wanted to improve the law on artisans' dwellings, and by Dr. FRANCISCO NAMORADO who advocated vegetarianism.

The Resolutions of the Section of Hygiene.

The President then laid upon the table a large number of papers which should have been read to the section. Their authors, however, were not present; and even if they had responded when their names were called there remained insufficient time to hear them. The President now submitted to the vote the various motions that had been introduced in the section during the course of the debates. First, a motion was adopted recommending the creation of anti-tuberculosis dispensaries to serve as centres of treatment, of education for the prevention of the disease, and for the early detection of cases. Then a motion was approved in favour of compulsory disinfection under the control of State officials in cases of infectious and contagious disease.

Opposition was made to a proposal demanding the convocation of an international conference on plague so as to help to find the methods and the money to combat this disease.

Dr. LOEFFLER said that various nationalities had sent out expeditions to investigate this matter, notably France, Austria, and Russia, and he doubted whether anything more was necessary.

The PRESIDENT replied that though many countries had made national scientific inquiries an international effort was now perhaps necessary.

A DELEGATE objected that after all the principal seat of plague was British India, and what would the British Government say to the proposal?

Mr. SMITH remarked that what the British authorities needed was some means of overcoming the religious prejudices of the native Indian populations which rendered it almost impossible to enforce the means of checking plague which an international commission would probably recommend. The matter then dropped and no motion was put.

A motion was brought forward to protect workers, especially in unwholesome and injurious industries, and an amendment was carried to the effect that legislation for the protection of labour should, so far as possible, be the same in all nations so as to prevent the cause of humanity suffering from the exigencies of competition.

With a vote of thanks to the presiding officials the section then terminated its labours.

LEGAL MEDICINE.

Professor ADRIANO X. LOPES VIEIRA, superintendent of the Morgue at Coimbra, read a paper upon

The Signs of Death by Drowning.

He said that one of his principal objects was to consider whether in the case of a dead body found in water the death was due (1) to asphyxia consequent on the immersion, or (2) to some other cause. Most writers on legal medicine believed that in these circumstances death not due to asphyxia was rare but Professor Vieira, on the contrary, believed it to be relatively frequent. Among the small number of writers who had given attention to the subject of death due to syncope as distinguished from death due to asphyxia he mentioned Dixon Mann and Vivian Poore in England, Strassmann in Berlin, Vibert in Paris, and Witthauss and Becker and Peterson and Haines in North America. After reviewing the classical signs of death from drowning he said that they were not invariably present. Moreover, when death was not due to asphyxia—that was to say, when death took place suddenly so that the person had no time either to draw water into the lungs or to swallow it—the post-mortem appearances which resulted from such drawing of water into the lungs or swallowing it must be absent. At present there was hardly any means of determining whether death in such circumstances was due to respiratory syncope or to cardiac syncope or to meningo encephalic congestion or hæmorrhage. As illustrating his views he described a case in which the body of an infant was found in a well near Coimbra. The parents when brought to trial said that the body was not thrown into the well until after the infant had died a natural death in their arms. The body was that of a healthy infant, there were no signs of strangulation, and the post-mortem appearances did not warrant the making of a more definite statement than that death might have been due to respiratory syncope. The parents were therefore acquitted.

THE GERMAN SURGICAL CONGRESS.[1]

THE German Surgical Association held its annual meeting in Berlin from April 4th to 7th, Professor KÖRTE (Berlin) being in the chair. In his inaugural address the chairman alluded to the ever-increasing number of members and said that in former times the progress of medical science depended mainly on the work accomplished by men holding appointments at the universities, but the great hospitals were now to some extent making their influence felt in this respect. The first day of the meeting was almost exclusively devoted to military surgery, a subject which has undergone great development owing to the recent Russo-Japanese war.

Military Surgery.

Professor ZOEGE VON MANTEUFFEL (Dorpat in Russia) read a paper describing his experiences of first aid on the battlefield. He spoke of the difficulties encountered in establishing dressing stations, difficulties which were due to the very long range of modern projectiles. The dressing stations, and still more the moveable field hospitals, must therefore be placed at a great distance from the scene of the engagement. A large number of transport vehicles was essential and the hospitals should be established as near as possible to the railway stations so as to facilitate the subsequent removal of the wounded. With regard to the nature of the wounds coming under treatment he said that wounds caused by shells were not often seen because they were liable to prove fatal at once. Shrapnel wounds, on the other hand, were rather frequent and their action differed very much in individual cases. Once, for instance, the thorax and the vertebral column were perforated, in another instance 11 bullets were found under the skin of the face. They nearly always tore the man's clothes and drove the pieces into the wound so that the latter became contaminated. Shrapnel was therefore more dangerous than rifle bullets which produced simple wounds of entrance and exit. An explosive action was never observed. Professor von Manteuffel then spoke of the number of cases which must be expected to occur. Generally one-third of the force engaged was put out of action and of these men the fourth part were either dead or missing while the remainder were wounded. In the battle of Mukden 62,000 out of 280,000 combatants were wounded. The surgeons had to work especially at night and on an average from 100 to 120 wounded were dressed by each surgeon. The dressing material which the soldiers carried with them proved to be very useful; the temporary dressing done by the comrades of the wounded was often so good that no change was necessary. In shrapnel wounds and wounds passing directly through the skull the conservative method proved to be the best. In tangential wounds of the skull, however, in which pieces of the man's cap, hair, or splinters of bones were often present, the wound had to be cleansed and the apertures of entrance and exit joined by chiselling away the intervening bridge of bone. Wounds of the trachea and of the œsophagus were treated by conservative methods exclusively and so also were wounds of the lungs, the head, and the vertebral column The patients suffering from wounds of the vertebræ often died from cystitis caused by the use of dirty catheters during transport Abdominal wounds were only to be dressed externally and no operations were to be performed in the dressing station. In wounds of the extremities plaster bandages were to be applied and if an amputation became necessary the stump was not to be sutured.

---

[1] For this report we wish to tender our sincere thanks to the editor of the *Deutsche Medizinische Wochenschrift*, through whose courtesy it has been forwarded to us by our Berlin correspondent.

Dr. Schäfer of the German Red Cross Society said that the number of men put out of action was on an average 16 per cent., but was sometimes 21 per cent. In some regiments which took part in several battles the proportion of losses rose to 95 per cent. Of 100 wounded on an average 44 were put out of action, the proportion between deaths and wounded being 1 to 5. Of the wounded only 2 per cent. died; the proportion of slight wounds was therefore considerable and 45 per cent. of them were able to take part again in the war. In some instances men who were wounded three, four, or even five times returned to the ranks—a splendid testimonial to the bravery of the Russian soldier. Dr. Schäfer concluded by saying that the urgent question to be solved in future wars would be the transport of the wounded.

Dr. Goldammer (Hamburg) read a paper on the War in German South Africa. The circumstances of this war differed from those of the Russo-Japanese war because the number of patients was relatively small, but the great distances which separated the combatants from the field hospitals and the base hospitals made the transport of the wounded very difficult. Disinfection of wounds was impossible owing to the deficiency of water-supply and dry dressing was therefore the method used in the majority of cases. When there was no urgent indication for an operation a piece of iodoform gauze was put on the wound and fixed by adhesive plaster. The gauze soon became dry, the edges of the wound adhered to one another, and when the patient was being removed a gauze bandage could be applied, for with compound fractures the application of a splint was essential for transport.

Dr. Bornhaupt (Riga) presented a report on wounds of the joints. He said that his hospital was at the railway-station in Harbin, six days' journey from the theatre of war, and that he had treated 167 cases, being 78 per cent. of all the wounds in question; wounds of the knee were the most frequent, then came those of the ankle and the shoulder. Suppuration occurred most frequently in the ankle, whilst simple wounds of the knee-joint usually healed without reaction. Of non-suppurating joints 93 per cent. healed without reaction and in the case of the knee-joint even 100 per cent. Patients not suffering from reaction were sometimes able to get up on the fifth day. In 23·6 per cent. of the cases operations were performed chiefly on account of suppuration, shell wounds of the hip-joint and the knee showing the greatest mortality.

Dr. Brentano (Berlin) read a paper on wounds of the blood-vessels. He said that primary operations on blood-vessels were impossible on the battlefield and could only be performed in the field hospital. Aneurysms were of frequent occurrence and had to be dealt with subsequently by operation. He showed a specimen consisting of an aorta perforated by a bullet; notwithstanding the serious nature of the injury the patient lived for a whole day.

Dr. Colmers (Leipsic) read a paper on compound fractures caused by artillery or rifle fire. He recommended that no attempts at disinfection should be made but that occlusive dressings and plaster bandages should be applied.

Dr. Henle (Breslau) and Dr. Hildebrandt (Berlin) spoke of injuries of the nerves and of the skull.

Dr. von Oettingen (Berlin) remarked that projectiles coming from a distance of about 300 metres made small entrance and exit wounds but there might at the same time be severe lacerations of the viscera. As even in extensive injuries adhesions might eventually occur the treatment must be strictly conservative, prolapses and incarcerations of course excepted.

In the discussion Dr. von Wreden (St. Petersburg), a representative of the Russian Army Medical Corps, opposed the opinion that the modern rifle was more humane than the older form. He said that the new rifle was by far the more deadly of the two.

Operations on the Thyroid Gland.

Professor Kocher (Berne) read a report on the third series of 1000 operations for extirpation of the thyroid gland performed by him, the death-rate being 0·1 per cent. These cases included 35 of malignant disease, eight of inflammation of the gland, 52 of Graves's disease, and 904 of ordinary excision. The operation itself was not dangerous provided that the heart was healthy; in Graves's disease the operation must be performed as early as possible. Careful ligature of the blood-vessels with sterilised silk was essential. The internal administration of iodine or of thyroid preparations was useless.

Operations for Gastric Ulcer.

Professor Krönlein (Zürich) said that the results of internal treatment in this condition were far from being satisfactory. At the meeting of the German Surgical Congress in 1897 Professor Leube had stated that internal and dietetic treatment had been unsuccessful in 7·9 per cent, death occurring in 2·4 per cent. only. These numbers were, in Professor Krönlein's opinion, misleading because they took into account only the immediate results without regarding the sequelæ Other statistics published by Dr. Warren of Boston and Dr. Schulz of Breslau showed that internal treatment was unsuccessful in about 25 per cent. of the cases and that there were from 10 to 13 per cent. of deaths. Although the cases coming under surgical treatment were much graver, because in a good many of them internal treatment had previously been used without success, the ultimate results were that in 85 per cent. a complete and permanent recovery was obtained. The death-rate was from 8 to 10 per cent.; on an average 3 per cent. died afterwards, especially from cancer. The object of the operation was to produce a cicatrisation of the ulcer and a restitution of the normal function of the stomach. Total resection of an ulcer was not often practicable because the ulcers were not infrequently multiple. Gastro-enterostomy, moreover, by creating a new way between the stomach and the intestines, and so removing the ingesta quickly, prevented them from decomposing. Gastro-enterostomy should, therefore, be the normal operation and should be preferred to gastrectomy. The indications for the operation were the failure of internal treatment, stenosis of the pylorus, gastrectasis, and repeated hæmorrhage. In profuse hæmorrhage the operation should be postponed until the patient had somewhat recovered.

Professor Rydygier (Lemberg) said that resection of the ulcers was preferable to gastro-enterostomy because the condition of the stomach became normal. Moreover, resection prevented the formation of peptic ulcers of the stomach and removed callous edges. He said that he had lost two of his cases of gastro-enterostomy from profuse hæmorrhage and two cases from perforation and he suggested that these complications were probably not infrequent. By resection of the ulcers the development of cancer was avoided.

Dr. Kümmell (Hamburg) said that ulcers were not liable to become cancerous when the irritation caused by the ingesta had been removed by gastro-enterostomy. The great difficulty and the long duration of resection made this operation dangerous, especially in weak patients.

Professor Körte (Berlin) reported 36 perforations, of which 24 occurred into the abdominal cavity, while 12 were subphrenic. After resection he had known ulcers to recur on two occasions and hæmorrhage once. His operative results had recently become better because he operated at an earlier stage.

(To be continued.)

MEDICINE AND THE LAW.

An Unfounded Charge Dismissed.

THE extraordinary prosecution brought against Dr. Alfred Ernest Jones by two mentally defective little girls whom he had examined as one of the medical officers of the London County Council with a view to provision for their suitable education has been dismissed. The result was a foregone conclusion so far as ultimate acquittal was concerned, but Dr. Jones is to be congratulated upon having had the preliminary stages of such an accusation heard before a metropolitan police magistrate whose wide experience in criminal charges of all kinds enabled him to take with confidence a course which members of other benches less used to exercise their discretion vigorously and promptly might have hesitated to adopt. The charge was one which on the face of it was either entirely without foundation, or one which, if the facts were proved, would have shown that a lunatic asylum must be the only fit place for the accused. Dr. J. Kerr made inquiry and saw that no reliance could be placed on the preposterous statements of the children, but the parents, not satisfied with his conclusion that there was nothing to justify the matter being taken further, with more zeal on behalf of their offspring than discretion or charity towards Dr. Jones, insisted upon the police intervening. The case has since had a fair and prolonged hearing in open court and if the evidence led the magistrate to the conclusion that no jury would dream of convicting upon it, it must also have brought home to all the most insidious perils that a medical man is called upon to undergo in the pursuit of his profession. He cannot always have a third person present, even whenever he may be called upon to make inquiries and examinations likely to suggest hideous accusations of immorality to the diseased mind of his patient. In such a case as that now commented upon he probably would not think of doing so. Now, however, with this recent experience to recommend every precaution possible, it may be pointed out that in many instances where the interview is one conducted in an official capacity it will usually be easy to secure the presence of a matron or a nurse. Dr. Jones should be the recipient of warm congratulation, followed by prompt oblivion that any such charge ever hung over his head.

A Quack Medicine Company and its Advertisements.

In an action tried recently by Mr. Justice Lawrance in the King's Bench Division a firm of advertising agents sued "The Kouvo Manufacturing Company" for £126 in connexion with the insertion of advertisements in provincial newspapers. The subject of the advertisements was a quack remedy for rheumatism, the orders for their insertion being given by a Mr. Cowood, manager of the company at Leeds, cheques paid on account being signed by a Mr. Henry Watson. When, however, the advertisement agents asked for a settlement of the balance owed to them they were told that there was no such company as "The Kouvo Manufacturing Company" and the defence alleged that the business was that of another company entitled the Danish Siberian Produce Company, which was in liquidation, Mr. Watson being apparently the liquidator. With regard to this gentleman Mr. Justice Lawrance observed that he had been reading the affidavit made by him and that anything more misleading he had never seen, adding that he should have liked to see Mr. Watson in the witness-box, as in the document before the court there was nothing to show that he had had previous knowledge of the transactions referred to or was other than a liquidator brought in as such from outside. His lordship's observations on the conduct of the defendants in the matter before him were of an extremely severe character; he characterised it as a swindle and after the defendants' counsel had declined to go further with the defence before his lordship he gave judgment for the plaintiffs with costs, ordering also that the defendants should declare who was responsible for payment to the plaintiffs. He refused a stay of execution and declined to give leave to appeal against the order mentioned. As an appeal, nevertheless, may be contemplated with regard to the case itself further comment upon it would be premature. We may say, however, that we should in the circumstances be prepared to express no sympathy either with the plaintiffs or with the defendants. The advertisements of quack medicine vendors in general are concocted with a view to selling articles which do not possess the qualities assigned to them and which have an intrinsic value immeasurably below the price at which they are sold. The business may be a paying one—in many instances we have no doubt that it is so—but advertisement agents who traffic with the purveyors of such rubbish, relying upon their credit, are not unlikely to find themselves losers by the transaction.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

AN ordinary meeting of the Council was held on May 10th, Mr. JOHN TWEEDY, the President, being in the chair.

Surgeon-General Arthur Mudge Branfoot, C.I.E., and Director-General Herbert Mackay Ellis, R.N., were introduced and after signing the by-laws and making the required declaration were admitted Fellows of the College.

Mr. Reginald Cheyne Elmslie was introduced and the President handed to him a cheque for the amount of the Jacksonian prize for the year 1905, together with a document declaratory of the award.

Mr. Walter Burford Johnson was introduced and signed the Roll of Begley Students and the President handed to him a cheque for the first year's payment in respect of his studentship and a document certifying his appointment as Begley student.

It was resolved to issue Diplomas of Membership to 102 successful candidates.

A letter was read from Dr. J. Ward Cousins presenting his report as the representative of the College on the Central Midwives Board. The report showed that during the past year 20 meetings of the Board have been held, that 18 examiners for London and 16 for the provinces have been appointed, and that three examinations have taken place. In all there have been 1256 candidates, of whom 956 have passed and 300 have been rejected. The Board has recognised 63 training schools and the number of teachers appointed amounts to 128. Up to April 1st, 1906, 23,166 women have been admitted to the Midwives Roll; of this number 22,210 were certified under the provision for existing midwives in *bonâ-fide* practice prior to April 1st, 1905, and 956 have passed the examination of the Central Midwives Board. The disciplinary proceedings of the Board have resulted in the removal of 14 midwives from the Roll and seven others have been severely censured. The county councils and the county borough councils of England and Wales are only slowly carrying out the provisions of the Midwives Act of 1902. 33 of the county councils have not yet appointed a medical executive officer. The councils of 23 counties have appointed inspectors of midwives, and in eight English and five Welsh counties the Act is stated to be administered wholly by the local supervising authority without the assistance of any medical officer or inspector. In a few counties the duties of inspector are performed by the county or district medical officer. 42 of the county borough councils have not yet decided to appoint an inspector of midwives. In 28 county boroughs the medical officer of health or a female inspector has been selected to discharge these important duties. At Manchester a qualified female practitioner is the local inspector and at Liverpool the ex-matron of the lying-in hospital has been appointed to the office. Dr. Cousins also pointed out that evidence of elementary education of candidates should be required of all pupil-midwives before the commencement of their training; and concluded his interesting report as follows: "I regret to state that Liverpool and Cardiff are the only centres where the councils have made any arrangement for the payment of medical men summoned to assist midwives in cases of difficulty and danger. By the Act the profession is practically responsible for the safety of the poor parturient women of the country, and yet it contains no provision to secure payment for professional services."

The best thanks of the Council were given to Dr. Cousins for his services as the representative of the College.

It was resolved to suspend the rule relating to the meetings of Fellows (the effect of this is that the annual meeting of Fellows in July will not be held this year).

It was resolved to hold a Fellows' subscription dinner on Thursday, July 5th, the day of the Council election.

A letter was read from Professor Carl Olaf Jensen thanking the Council for the recognition accorded by it to his work in the field of cancer research by the award of the

Walker prize and expressing regret that it would be impossible for him to visit England and to express his thanks in person.

The PRESIDENT reported that after the receipt of Professor Jensen's letter he had communicated with the Honourable Sir Alan Johnstone, K.C.V.O., British Minister at Copenhagen, and that his Excellency had kindly undertaken to present the Walker prize to Professor Jensen on behalf of the Council.

A letter was read from Dr. Just Lucas-Championnière thanking the Council for the honour which it had conferred upon him in making him an Honorary Fellow.

A letter was read from Lieutenant-Colonel Sir R. Havelock H. R. Charles, I.M.S., K.C.V.O., thanking the Council for awarding to him the honorary medal of the College and expressing his high appreciation of the honour conferred upon him.

The PRESIDENT reported that in pursuance of the resolution adopted by the Council at its last meeting he had appointed Dr. H. Timbrell Bulstrode a representative of the College, in association with Mr. Edmund Owen, on the general organising committee for the Second International Congress on School Hygiene.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 6676 births and 4698 deaths were registered during the week ending May 12th. The annual rate of mortality in these towns, which had been equal to 17·3, 16·7, and 16·3 in the three preceding weeks, further declined last week to 15·5. The mean death-rate in these towns during the first six weeks of the current quarter was 16·7 per 1000; in London it was 17·0. The lowest death-rates during last week in the 76 towns were 6·5 in King's Norton, 6·7 in Northampton, 6·9 in Walthamstow, 7·2 in Hornsey, and 7·4 in Handsworth; the rates in the other towns ranged upwards to 20·5 in Liverpool and in Salford, 21·0 in Bradford, 21·3 in Bury and in Rotherham, and 23·1 in Barrow-in-Furness. The 4698 deaths in the 76 towns showed a further decline of 256 from the numbers in recent weeks and included 484 which were referred to the principal infectious diseases, against 519, 484, and 482 in the three preceding weeks; of these, 218 resulted from measles, 123 from whooping-cough, 47 from scarlet fever, 37 from diphtheria, 42 from diarrhœa, 17 from "fever" (principally enteric), and not one from small-pox. The deaths from these diseases were equal to an annual rate of 1·6 per 1000 in the 76 towns and the rate was the same in London. No death from any of these infectious diseases was registered last week in Nottingham, St. Helens, Bury, Rochdale, Hastings, or in six other of the large towns, whereas they caused the highest death-rates in Manchester, Salford, Liverpool, Bradford, Yarmouth, and Burnley. The highest death-rates from measles occurred in Liverpool, Bradford, Yarmouth, and Burnley; from whooping-cough in Reading, Bootle, Huddersfield, Coventry, and Warrington; from scarlet fever in Sheffield and Rotherham; and from diphtheria in Hornsey and York. The 42 deaths attributed to diarrhœa in the 76 towns showed a slight increase, while those referred to "fever" showed a decline. Only one case of small-pox remained under treatment in the Metropolitan Asylums Hospitals at the end of last week, and no new case was admitted during the week. The number of scarlet fever cases under treatment in these hospitals and in the London Fever Hospital on Saturday, May 12th, was 2378, showing a further increase upon the numbers in recent weeks; the 338 new cases admitted during the week were fewer by 19 than the number in the previous week. The deaths referred in London to pneumonia and other diseases of the respiratory organs, which had been 399, 351, and 309 in the three preceding weeks, further declined to 273 in the week under notice, but exceeded by 34 the corrected average for the corresponding week in the four preceding years, 1902–05. The causes of 56, or less than 1 per cent., of the deaths registered in the 76 towns during the week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Leeds, Sunderland, Newcastle-upon-Tyne, and in 47 smaller towns. The proportion of uncertified deaths showed, however, an excess in Birmingham, Liverpool, Warrington, Bradford, and Gateshead.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 18·4 and 18·0 per 1000 in the two preceding weeks, rose again to 18·8 in the week ending May 12th, and exceeded by 3·3 the mean rate during the same week in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·2 and 16·5 in Paisley and Aberdeen to 19·9 in Glasgow and in Greenock, 20·2 in Dundee, and 22·7 in Perth. The 645 deaths in these eight towns included 26 which were referred to measles, 16 to whooping-cough, 15 to diarrhœa, seven to diphtheria, two to scarlet fever, one to "fever" (probably enteric), and not one to small-pox, although a death in Edinburgh was attributed to chicken-pox. In all, 67 deaths resulted from these principal infectious diseases, a decline of three from the number in the previous week. These 67 deaths were equal to an annual rate of 2·0 per 1000, which exceeded by 0·4 the mean rate during the week from the same diseases in the 76 large English towns. The 26 fatal cases of measles in the Scotch towns showed a further increase upon the numbers returned in recent weeks and included nine in Glasgow, eight in Edinburgh, six in Leith, and three in Dundee. The 16 deaths from whooping-cough were fewer by five than the number in the previous week; 12 occurred in Glasgow and two in Edinburgh. Of the 15 deaths attributed to diarrhœa, an increase of two upon the number in the previous week, nine were returned in Glasgow and two in Paisley. The seven deaths from diphtheria included three in Glasgow and two in Edinburgh; the two fatal cases of scarlet fever occurred in Edinburgh; and the death from "fever" in Glasgow. The deaths referred in the eight towns to diseases of the respiratory organs, including pneumonia, which had been 135 and 138 in the two preceding weeks, declined last week to 109 but exceeded by two the number referred to these diseases in the corresponding week of last year. The causes of 19, or nearly 3 per cent., of the deaths registered in the eight towns during the week were not certified, the proportion of uncertified deaths in the 76 large English towns during the same week being less than 1 per cent.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 28·1, 22·4, and 25·9 in the three preceding weeks, declined to 21·7 in the week ending May 12th. During the first six weeks of the current quarter the death-rate in the city averaged 23·8 per 1000, against 17·0 in London and 18·6 in Edinburgh. The 158 deaths of persons belonging to Dublin registered during the week under notice showed a decline of 30 from the number returned in the previous week; they included eight which were referred to the principal infectious diseases, against ten and two in the two preceding weeks. The eight deaths from these infectious diseases included three fatal cases of "fever" (probably enteric), three of diarrhœa, and one each of measles and whooping-cough; they were equal to an annual rate of 1·1 per 1000, the rate from these diseases in the same week being 1·6 in London and 2·4 in Edinburgh. The 158 deaths in Dublin last week included 26 of infants under one year of age and 57 of persons aged upwards of 60 years; the deaths of infants exceeded the number in any recent week, while those of elderly persons were fewer by two than the number in the previous week. Three inquest cases and one death from violence were registered; and 67, or 42 per cent., of the deaths occurred in public institutions. The causes of three, or nearly 2 per cent., of the deaths were not certified either by a registered medical practitioner or by a coroner.

VITAL STATISTICS OF LONDON DURING APRIL, 1906.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 5·9 per 1000 of the population, estimated at 4,721,217 persons in the middle of the year. In the three preceding months the rates had been 6·7, 6·4, and 5·7 per 1000 respectively. The lowest rates last month were recorded in the City of Westminster, Islington,

ANALYSIS OF SICKNESS AND MORTALITY STATISTICS IN LONDON DURING APRIL, 1906.

(*Specially compiled for* THE LANCET.)

CITIES AND BOROUGHS.	Estimated population in the middle of 1906.	NOTIFIED CASES OF INFECTIOUS DISEASE.											DEATHS FROM PRINCIPAL INFECTIOUS DISEASES.											Deaths from all causes.	Death-rate per 1000 living.	Deaths of infants under one year to 1000 births.
		Small-pox.	Scarlet fever.	Diphtheria.*	Typhus fever.	Enteric fever.	Other continued fevers.	Puerperal fever.	Erysipelas.	Cholera.	Total.	Annual rate per 1000 persons living.	Small-pox.	Measles.	Scarlet fever.	Diphtheria.*	Whooping-cough.	Typhus fever.	Enteric fever.	Other continued fevers.	Diarrhœa.	Total.	Annual rate per 1000 persons living.

* Including membranous croup

Shoreditch, Poplar, and Camberwell; and the highest rates in Hammersmith, Chelsea, the City of London, Bethnal Green, Bermondsey, Wandsworth, and Deptford. One case of small-pox was notified last month, against six and seven in the two preceding months; this case belonged to Poplar. Six small-pox patients remained under treatment in the Metropolitan Asylums hospitals at the end of last month, against five and ten at the end of the two preceding months. The prevalence of scarlet fever showed a considerable increase over that recorded in the preceding month; the greatest proportional prevalence of this disease occurred in Paddington, Hampstead, the City of London, Bermondsey, Battersea, and Deptford. The Metropolitan Asylums hospitals contained 2192 scarlet fever patients at the end of last month, against 2866, 2580, and 2353 at the end of the three preceding months; the weekly admissions averaged 282, against 296, 271, and 238 in the three preceding months. Diphtheria was rather less prevalent in April than it had been in the preceding month; among the various metropolitan boroughs this disease showed the greatest proportional prevalence in Hammersmith, Chelsea, Stoke Newington, Bermondsey, Wandsworth, Greenwich, and Woolwich. The number of diphtheria patients in the Metropolitan Asylums hospitals, which had been 867, 926, and 924 at the end of the three preceding months, had further declined to 860 at the end of last month; the weekly admissions averaged 103, against 121, 116, and 111 in the three preceding months. The prevalence of enteric fever showed a slight decline from that recorded in the preceding month; this disease was proportionally most prevalent in Fulham, St. Pancras, the City of London, Wandsworth, and Deptford. There were 56 enteric fever patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 95, 79, and 65 at the end of the three preceding months; the weekly admissions averaged 11 last month and in each of the two preceding months. Erysipelas was proportionally most prevalent in Hammersmith, Hackney, Finsbury, Bethnal Green, and Shoreditch. The 24 cases of puerperal fever notified during the month included three each in Fulham, Stepney, and Wandsworth, and two each in Kensington, Chelsea, and Battersea.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in public institutions having been distributed among the boroughs in which the deceased persons had previously resided. During the four weeks ending April 28th 6170 deaths of persons belonging to London were registered, equal to an annual rate of 17·0 per 1000; in the three preceding months the rates had been 16·0, 15·9, and 16·2 per 1000. The death-rates last month ranged from 12·7 in Lewisham, 13·1 in Hampstead, 13·4 in Wandsworth, 13·6 in Woolwich, 14·0 in Fulham, and 14·4 in Paddington; the highest rates were 19·9 in Holborn, 20·2 in Bethnal Green, 21·4 in Southwark, 21·9 in Bermondsey, 22·2 in Finsbury, 23·2 in Shoreditch, and 26·4 in Chelsea. The 6170 deaths from all causes in London last month included 610 which were referred to the principal infectious diseases; of these, 293 resulted from measles, 40 from scarlet fever, 52 from diphtheria, 158 from whooping-cough, nine from enteric fever, one from ill-defined pyrexia, and 57 from diarrhœa. The lowest death-rates from these diseases were recorded in the City of Westminster, St. Marylebone, Hampstead, Lambeth, and Woolwich; and the highest rates in Chelsea, Holborn, Finsbury, Shoreditch, Bermondsey, Deptford, and Greenwich. The 293 deaths from measles were 40 in excess of the corrected average number in the corresponding periods of the four preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Kensington, Chelsea, Islington, Hackney, Finsbury, Shoreditch, and Bermondsey. The 40 fatal cases of scarlet fever were slightly in excess of the corrected average number; the greatest proportional mortality from this disease occurred in Paddington, Hammersmith, Chelsea, Holborn, and Bermondsey. The 52 deaths from diphtheria were 13 below the average for the corresponding periods of the four preceding years; this disease was proportionally most fatal in Fulham, Chelsea, Bermondsey, Wandsworth, Greenwich, and Lewisham. The 158 fatal cases of whooping-cough were 33 below the corrected average number; among the various metropolitan boroughs the mortality from this disease was proportionally greatest in Chelsea, Finsbury, Shoreditch, Poplar, Bermondsey, Deptford, and Greenwich. The ten deaths referred to "fever" showed a decline of six from the corrected average number: one fatal case of ill-defined pyrexia was recorded in the City of Westminster, and one of enteric fever in each of the following boroughs: Kensington, Fulham, St. Pancras, Islington, Hackney, Finsbury, Lambeth, Battersea, and Wandsworth. The 57 fatal cases of diarrhœa were slightly below the average number in the corresponding periods of the four preceding years; among the various metropolitan boroughs this disease was proportionally most fatal in Shoreditch, Stepney, Battersea, Southwark, Camberwell, and Deptford. In conclusion, it may be stated that the aggregate mortality in London last month from the principal infectious diseases was nearly 10 per cent. below the average.

Infant mortality, measured by the proportion of deaths among children under one year of age to registered births, was equal to 114 per 1000. The lowest rates of infant mortality were recorded in Paddington, St. Marylebone, Hampstead, Holborn, the City of London, and Wandsworth; and the highest rates in Chelsea, Stoke Newington, Hackney, Shoreditch, Southwark, Camberwell, and Deptford.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet Surgeon E. J. Morley to the *Ganges*, for Shotley Barracks. Surgeons: J. R. A. Clark-Hall to the *Robin*; J. P. H. Greenhalgh to the *Moorhen*; and R. H. St. B. E. Hughes to the *Vernon* for the *Niger*.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Lieutenants to be Captains (dated March 1st, 1906):—Arthur B. Smallman, Wentworth F. Tyndale, C.M.G., Percival Davidson, D.S.O., William F. Ellis, John McKenzie, Norman D. Walker, Arthur H. Hayes, Henry J. Crossley, Ralph B. Ainsworth, Charles A. J. A. Balck, Reginald Storrs, Raymond L. V. Foster, Frederick A. H. Clarke, George A. K. H. Reed, John W. S. Seccombe, John M. H. Conway, Sydney M. W. Meadows, Herbert V. Bagshawe, Dudley S. Skelton, Charles V. B. Stanley, Hugh G. S. Webb, William W. Browne, Richard Rutherford, William D. C. Kelly, Norman E. J. Harding, and Robert J. Franklin.

INDIAN MEDICAL SERVICE.

The King has approved of the following promotions among officers of the Indian Medical Service and admissions to the Service:—To be Colonel: *Bombay:* Lieutenant-Colonel (temporary Colonel) William George Hume Henderson (dated Nov. 11th, 1905). Captains to be Majors: *Bengal:* Cecil Robert Stephens, Leonard Rogers, and Gordon Travers Birdwood (dated Jan. 30th, 1905); Cecil Charles Stuart Barry, Ernest Alan Robert Newman, J. Gould, Reginald George Turner, James Davidson, and John Mulvany (dated July 29th, 1905); George Yeates Cobb Hunter (dated Nov. 17th, 1905). *Madras:* Eric Harding Sharman and Thomas Howard Foulkes (dated Jan. 30th, 1905); Thomas Stodart, Bhola Nauth, Alfred Eugène Berry, and Herbert St. John Fraser (dated July 29th, 1905). *Bombay:* Hugh Bennett (dated July 24th, 1905). The promotion of Major P. P. Kilkelly is antedated from July 29th, 1905, to Jan 30th, 1905. Lieutenants to be Captains: William Samuel Jagoe Shaw, Charles Seymour Parker, Harold Holkar Broome, Frederick Norman White, Charles Gibbons Seymour, Davis Heron, Thomas Corrie Rutherfoord, Henry Crewe Keates, Leethem Reynolds, Ernest Charles Taylor, Richard Arthur Needham, Dwarka Prasad Goil, James Kirkwood, and Alfred Whitmore (dated Jan. 31st, 1906). To be Lieutenants: Carl Henry Reinhold, Arthur Falconer Hayden, Broderick Edward Middleton Newland, Lewis Albert Hodgkinson Lack, Edgar John Cecil McDonald, Kenneth William Mackenzie, William Dundas Wright, John Francis Boyd, Vernon Northwood Whitamore, John Catto, Narindra Singh Sodhi, William Jackson Powell, and William Cowan Gray (dated Sept 1st, 1905).

The King has also approved of the retirement from the service of the undermentioned officer: Lieutenant-Colonel Shambhu Chandra Nandi (dated Dec. 6th, 1905).

ROYAL ARMY MEDICAL CORPS (MILITIA).

Captain and Honorary Major (Honorary Captain in the

Army) A. H. Benson resigns his commission, with permission to retain his rank and to wear the prescribed uniform (dated May 12th, 1906).

IMPERIAL YEOMANRY.

Herts: Surgeon-Lieutenant F. E. Fremantle to be Surgeon-Captain (dated May 12th, 1906).

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Argyll and Bute: John Stewart to be Surgeon-Lieutenant (dated May 12th, 1906). 3rd Lancashire: Surgeon-Major M. J. Fox is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated May 12th, 1906). 1st Sussex: Surgeon-Lieutenant H. H. E. Scatliff resigns his commission (dated May 12th, 1906); Harold Harris Elborough Scatliff (late Surgeon-Lieutenant) to be Second Lieutenant (dated May 12th, 1906).

Royal Engineers (Volunteers): 1st Sussex: Antony Alexander Martin to be Surgeon-Lieutenant (dated April 10th, 1906.

Rifles: 3rd Volunteer Battalion the Cheshire Regiment: Surgeon-Major T. Fennell is granted the honorary rank of Surgeon-Lieutenant-Colonel (dated May 12th, 1906). 1st Volunteer Battalion, the Durham Light Infantry: Surgeon-Lieutenant A. J. Dale resigns his commission (dated April 9th, 1906). A. J. Dale (late Surgeon-Lieutenant) to be Lieutenant (dated April 9th, 1906). 5th (Glasgow Highland) Volunteer Battalion, the Highland Light Infantry: Surgeon-Major G. Bell Todd to be Surgeon-Lieutenant-Colonel (dated May 12th, 1906). 1st (Ross Highland) Volunteer Battalion, Seaforth Highlanders (Ross-shire Buffs, The Duke of Albany's): Surgeon-Lieutenant-Colonel J. Adam is borne as supernumerary whilst holding the appointment of Brigade-Surgeon-Lieutenant-Colonel, Senior Medical Officer, Seaforth and Cameron Volunteer Infantry Brigade (dated May 12th, 1906).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

North-East Lancashire Bearer Company: Captain T. Holt to be Major (dated May 12th, 1906.)

WEST AFRICAN MEDICAL STAFF.

The following appointments, dated May 5th, have been made to the West African Medical Staff:—Dr. P. H. MacDonald (Southern Nigeria), Dr. B. Moiser (Northern Nigeria), Dr. W. Rogers (Southern Nigeria), Dr. G. J. Pirie (Northern Nigeria), Mr. A. G. Eldred (Gold Coast), and Dr. H. Kramer (Gold Coast).

Mr. T. E. Rice, L.S.A., senior medical officer in Southern Nigeria, has been transferred to the Gold Coast, vice Mr. K. F. T. Buée, deceased.

Mr. G. J. Rutherford, M.R.C.S. Eng., L.R.C.P. Lond., medical officer in the Gold Coast, to be senior medical officer, Southern Nigeria, vice Mr. T. E. Rice, transferred.

DEATHS IN THE SERVICES.

Surgeon-General Charles Sibthorpe, C.B., I.M.S. (retired), on May 4th, aged 58 years. He joined the Indian Medical Service as assistant surgeon in 1870 and retired in 1900. He served in the Afghan War, 1879–80, with the Peshawar Valley Field Force (medal) and also in the Burmese Expedition, 1885–86, as staff-surgeon to the general officer commanding the expedition and later in medical charge of the headquarters Staff (mentioned in despatches, medal with clasp, and promoted to the rank of brigade-surgeon).

THE ROYAL INDIAN TOUR HONOURS.

The *London Gazette* officially announces that Lieutenant-Colonel Havelock H. R. Charles, I.M.S. (Bengal), professor of surgery at the Medical College, Calcutta, surgeon on the staff of the Prince of Wales during the recent visit of their Royal Highnesses the Prince and Princess of Wales to India, has been made a Knight Commander of the Royal Victorian Order. Fleet Surgeon Robert Hill, R.N., of H.M.S. *Renown*, has been made a Member of the Fourth Class of the same Order.

THE NEW SCHEMES OF ARMY ORGANISATION.

There are naturally an unwonted amount of interest and consideration being extended at the present time to army matters in general and schemes of military organisation. The impending changes will probably be of a very comprehensive and important nature and their consideration must involve numerous questions in which the medical profession, in common with the rest of the nation, will be either directly or indirectly concerned. In the first place, the Secretary of State for War has appointed a strong committee, with Viscount Esher, G.C.V.O., K.C.B., as chairman, to consider how best to give effect to the principles governing the organisation of the auxiliary forces into a territorial army, as described in the speech of the Secretary of State on Army Estimates in the House of Commons on March 8th, 1906. Mr. Haldane, it will be seen, is slowly but surely working out his and the Army Council's scheme of army reform and in attempting to accomplish this in a satisfactory way he is availing himself of all the advice and help which he can obtain by getting a number of military experts and men "of light and leading" to take part in the necessary preliminary deliberations. An interesting and instructive debate took place in the House of Lords on May 14th in connexion with the question of home defence raised by the Earl of Wemyss. The Earl of Portsmouth said that we had a mobilisation scheme under which it was hoped that we could mobilise as quickly as any continental nation. While very plainly dissociating himself from the "blue water extremists" he nevertheless desired to affirm the principle that the navy was, as it always had been, the natural guardian and the only trustworthy defence for the United Kingdom against oversea invasion. The Under Secretary for War also took occasion to add to our information as to the future position of the militia, the volunteers, and coast defence.

EXAMINATION FOR COMMISSIONS IN THE ROYAL ARMY MEDICAL CORPS.

An examination of candidates for not less than 40 commissions in the Royal Army Medical Corps will be held on July 26th and following days. Applications to compete should be made to the Secretary, War Office, 68, Victoria-street, London, S.W., not later than July 16th, on which date the list will be closed. *Candidates* who are over the regulation limit of age at the date of the examination will be permitted to deduct from their actual age any period of service in the field after Oct. 1st, 1899, that they could reckon towards retired pay and gratuity if such deduction will bring them within the age limit. The presence of candidates will be required in London from July 24th.

REPORT ON ARMY PROMOTION EXAMINATIONS.

A report signed by General Hutchinson, director of staff duties, has appeared setting forth the results of the examination for army promotion in November last, a summary of which has been published in the *Army and Navy Gazette* of last week. We pass over the papers set for, and the marks gained by, the combative ranks and turn to Appendix VIII., B, Majors R.A.M.C., from which we take the following as likely to prove useful and interesting to those concerned. "Army Medical Organisation.—The work submitted was very moderate. There was no undue difficulty in the paper and nothing to prevent a candidate acquainted with the subject from gaining 80 per cent. of the marks. Major C. J. MacDonald, M.D., was the only officer who obtained 0·8. Sanitation and Epidemiology.—The papers submitted in this subject were better than those on previous occasions though as a whole they are not very satisfactory. No officer gained 0·8 The questions were not such as could be answered simply by working up a textbook; they involved all-round practical knowledge and some considerable familiarity with current developments. Selected Subjects.—Major and Brevet Lieutenant-Colonel W. B. Leishman, M.B., and Major T. McCulloch, M.B., obtained 90 per cent. of the marks. Subjects (*h*) ii. and iii., Lieutenants R.A.M.C.—The results are satisfactory. Lieutenants R. L. V. Foster, M.B., M. G. Winder, and G. F. Rugg obtained 80 per cent. of the marks allotted."

REGIMENTAL HOMES.

The report of the Regimental Homes and Benefits Agency, dated April, 1906, published at 11, Tothill-street, Westminster, London, S.W., gives an interesting account of a scheme began in 1901 as a memorial to the late Prince Christian Victor of Schleswig-Holstein, the scope of which was extended in 1904 Briefly, the idea is to help regiments to build homes for disabled soldiers, the homes being the property of the regiments to which they are attached. 49 homes have already been completed and occupied and ten others are in course of building. As the report points out, this is not the first time that permanent homes for old soldiers have been established. The Warwick, Chelsea, and Kilmainham Hospitals were founded long ago. But it is the first time that the provision is made regimentally and in this respect the scheme is entirely new. Moreover, from the soldier's point of view, the difference is all-important; for he regards a home *established* by an agency outside his regiment as a charity, whereas his selection by his regiment as an inmate of one belonging to that regiment is considered a privilege and an honour.

Correspondence.

"Audi alteram partem."

THE INFAMOUS ACCUSATION AGAINST DR. A. E. JONES.

To the Editors of THE LANCET.

SIRS,—In your issue of May 5th you commented sympathetically upon the conclusion of the hearing of the charge against Dr. A. E. Jones of assault upon certain mentally defective children during his official examination of them at the London County Council day-school which they attend. Completely successful as was the result of the case, it was, of course, not accomplished without considerable expense which falls entirely upon Dr. Jones. Baseless charges of this kind are unfortunately only too well known to the profession which has always readily shown practical sympathy with the victims of an injustice to which all its members are equally exposed. This case, moreover, displays special features which call for more than usually energetic protest if the status of the profession is not to be seriously jeopardised. All are familiar with the class of persons by whom such false charges are usually brought, but this is the first time that an important public body has supported an accusation of this type which originated with mentally defective children, an accusation, *moreover*, which the magistrate dismissed without listening to the defence.

It is felt that a subscription to defray Dr. Jones's legal expenses (which amount to £180) would be the most satisfactory way of expressing the sympathy of the profession and of its intention to meet such attacks as a united body. A small committee, consisting of the undersigned, has been organised for this purpose and Sir Victor Horsley has consented to act as treasurer. Bearer cheques may be made payable to, and crossed, Barclay and Co., and sent to Messrs. Barclay and Co., 54, Lombard-street, E.C., or to Sir Victor Horsley, 25, Cavendish-square, London, W.

We are, Sirs, yours faithfully,
S. H. BOWN, CHARLES BOLTON,
P. MAYNARD HEATH, C. WYNN WIRGMAN.

May 16th, 1906.

The following subscriptions are announced:—

	£	s.	d.
Mr. Arthur E. J. Barker	5	5	0
Dr. J. Rose Bradford	5	5	0
Dr. Dudley W. Buxton	5	5	0
Sir Victor Horsley	5	5	0
Dr. Sidney H. C. Martin	5	5	0
Mr. Bilton Pollard	5	5	0
Dr. Herbert R. Spencer	5	5	0
Dr G. F. Blacker	3	3	0
Mr. Rupert T. H. Bucknall	2	2	0
Mr. Raymond Johnson	2	2	0
Mr M. D. Eder	1	1	0
Mr. E. S. Weymouth	1	1	0

CASEIN AND CASEINOGEN.

To the Editors of THE LANCET.

SIRS,—It is with mingled feelings of pleasure and amazement that I have read the letter of Professor W. D. Halliburton in reply to *my* protest; the pleasure comes from finding that some of the reasons given for the nomenclature are rational, concisely stated, and ones which I can accept. I am amazed, however, that Professor Halliburton should derive caseinogen *from the Latin*; the root of *genero* is not *gen*, but *gener*, and I think he will pardon me *for not* having recognised the Latin origin. Casein is not a Latin word, but judging from the gender of the French and Italian the Latinised form would be *caseina* and a more correct *name* would be "*caseinagenerin*" (I have given the word the termination "in" to indicate its proteid nature). Caseinogen as a word derived from the Latin is but little less objectionable than as a hybrid.

I am still more amazed that Professor Halliburton calls the instance of the confusion that arises *from* his nomenclature which I pointed out in Dr Gustav Mann's book an obvious press error; *in the index* Dr. Mann gives 50 references to casein and two to caseinogen (the word, however, occurs many times in the text in these two references); one and one only of the casein references is to casein in Professor Halliburton's sense, in two of them (pp. 70 and 353) the word caseinogen only and not casein is mentioned in the text, and *in the* bulk of, if not in all, the other 47 references the word casein is used obviously in the sense of caseinogen. One instance *especially* may be quoted in full (p. 378): "Fibrinogen, myosin, and casein assume a firm state of aggregation when acted on by certain ferments." This passage clearly shows not only is Professor Halliburton's nomenclature departed *from in "casein" but in "myosin" as well, and it* cannot be an "*obvious* press *error*" when two words are given in the old form. It is the tacit sub-conscious revolt of a scientific mind against what I have ventured to term a philologically barbarous nomenclature. I am again amazed *that Professor* Halliburton should speak of "antique terminology." Is he *aware that in the index of the Journal of the Chemical Society* for 1905, quite lately published, "*caseinogen*" does not occur, but the proteid to which he gives this name is called "casein"? Does he know that in the abstracts of the *Chemical Society*, except in those made by himself, the word "casein" has been used this year? Has he forgotten that in the January number (vol i., p. 56) he wrote, "A comparison of solutions of casein and para-casein (or as they are usually called in English caseinogen and *casein respectively*)......"? And is not this a tacit admission that "caseinogen" is still largely called "casein" and "casein" "para-casein"? Does not Dr. Thorpe, an ex-president of the Chemical Society and chief Government chemist, use "casein" (Transactions of the *Chemical Society*, 1905, pp. 214, 216) only last year?

Professor Halliburton *asks if* I *would propose to drop* the word "fibrinogen" and call it fibrin; my answer is that fibrin should be retained for the proteid to which it is at present applied; it has *priority* and *is universally accepted.* I should like fibrinogen dropped or modified. I *am glad to* hear that a joint committee of the Chemical and Physiological Societies has been appointed to consider proteid nomenclature but deplore their recommendation; I can only think that they have not had the case against the use of caseinogen put before *them*. I *may* say that I do not object to "caseinogenate" on account *of* its length, I cannot pronounce it euphoniously.

Finally, I would like to recapitulate *the chief* objections against "caseinogen": 1. *It is* "*philologically* barbarous." 2. Casein has priority. 3. It is far *from* universally used even in England and still less so in America. 4. The German "kasein," *the French* "caséine," and the Italian "caseina" are generally used and *the natural word* which occurs for the translation of these is "casein." (*The confusion* which exists is due to 3 and 4.) 5. It departs from the well-established rule of chemical nomenclature that similar compounds have the same termination. For this very proper reason the old terms "caseine" and "albumen" have been changed to "casein" and "*albumin*."

It would be quite easy to retain the advantages pointed *out* by Professor Halliburton and at the same time to abandon "*caseinogen*." I am, *Sirs, yours faithfully,*

H. DROOP RICHMOND.

Woodfield road, Ealing, W., May 12th, 1906.

To the Editors of THE LANCET.

SIRS,—As Mr. H. Droop Richmond *has* courteously sent me a copy of the letter *on* this question which *he is* forwarding to you for publication I am enabled *forthwith to* add a rejoinder. It shall be very brief and, so far as I am *concerned, final, for I* am well aware that your space is too valuable for discussions *of* this nature. I will only say that I am not convinced by Mr. Richmond's arguments and will refer those interested in the question to my letter of last *week*, as I find myself unable to state my own views any *more clearly than* I have put them there. The only statement there made which I should like to amend relates to what I said about Dr Gustav Mann's book. The *particular case* of confusion in the use of the two words under discussion, and which appeared to me to be a printer's error, is not, as Mr. *Richmond* correctly states, the only instance where the words are *wrongly employed*. I admit *that authors* as well as printers are occasionally careless, but I fail *to see in that* any reason for adopting Mr. Richmond's views. Physiologists *in this* country have practically unanimously accepted the words caseinogen and casein *in the* sense in which I have urged they should be used. I feel hopeful now that Mr. Richmond admits some of my reasons to be rational and acceptable to him that chemists also, when the "tacit subconscious revolt of their minds" has subsided, will fall into line also. When we have set our own house in order it will be time to try to persuade foreign nations to follow suit, and it is the intention of the proteid nomenclature committee, to which I referred last week, to obtain the opinion of other countries regarding their proposals before putting them forward in any authoritative manner.

I am, Sirs, yours faithfully,
W. D. HALLIBURTON.

King's College, London, May 14th, 1906.

THE TRANSMISSIBILITY OF GOITRE.

To the Editors of THE LANCET.

SIRS,—The following history seems interesting enough for publication. A perfectly healthy family came from a village near the Exe and settled here some 36 years ago. No member of the family, so far as they can tell, ever suffered from any enlargement of the neck previously to their coming here. There were three daughters. The youngest went to work at a farm in this village at 15 years of age and rapidly developed goitre. (Another help at the same farm has recently also developed goitre very rapidly.) She left the farm and married and the goitre has persisted but has not increased. Her first eight children were born healthy, the ninth had well-marked goitre and died in infancy from whooping cough, and the tenth, born last month, has also well-marked goitre. All the children were suckled and she is sure that the last two never drank any water at any time. The well water here is extremely hard and goitre was, it seems, very common before the present supply was instituted. It is practically extinct now and I know of no recently developed case except the one at the farm mentioned, which is one of the few places where they still drink well water.

The history is interesting, for it is impossible to doubt that she acquired goitre from a definite source and had apparently no hereditary tendency. After eighteen years, while no longer exposed to the poison, she seems to have communicated the complaint to her offspring. During the last two years she has not drunk any unboiled water by my advice and she has not drunk well water for several years. My books of reference say that goitre is occasionally hereditary and may occur in infancy, but I can find no case similar to the above, which seems to militate against the axiom which tells us that "Acquired peculiarities are not hereditary." It almost suggests that goitre poison is like syphilitic poison and may be acquired and passed on to the offspring.

I am, Sirs, yours faithfully,
O. CLAYTON JONES, M.B. Oxon.

Silverton, Devon, May 7th, 1906.

ANTERIOR OR POSTERIOR GASTRO-JEJUNOSTOMY?

To the Editors of THE LANCET.

SIRS,—In THE LANCET of May 12th, p. 1347, Mr. Edward Ward makes a claim, on Mr. H. Littlewood's behalf, to priority in two "essential features" of the operations of gastro-enterostomy and of intestinal anastomosis, "the use of rubber sheathed Doyen's clamps" and "the excision of elliptical portions of mucous membrane from each organ."

First, as to the use of the clamps. In Mr. Littlewood's paper to which Mr. Ward refers the mention of the clamps is merely incidental. The title of the paper—and it is important to note it—is "Intestinal Suture by Means of Continuous Catgut Stitch, and Excision of the Mucous Membrane." In his preamble Mr. Littlewood, after mentioning some of the mechanical aids used in affecting anastomoses, writes: "At the present time many surgeons have reverted to the earlier practice and have abandoned the use of any special apparatus, and I am amongst those" (implying obviously that he is only one among many) "who believe that all accessory apparatus for intestinal suture will ultimately be discarded and that we shall rely on our fingers, the forceps, and needles and sutures." There is not one word here or in any part of the paper which suggests that Mr. Littlewood considered that he was introducing any innovation in the matter of forceps. Mr. Littlewood himself, therefore, makes no claim whatever in this paper for any priority in the use of clamps in either stomach or intestinal work. Had he done so his claim could not have been substantiated. The use of the clamps in intestinal work was at least 20 years old when Mr. Littlewood wrote. Kocher in 1880[1] describes and illustrates with four figures his method of intestinal resection in which clamps were used. Mr. Thomas Smith (now Sir Thomas Smith) in THE LANCET of Nov. 18th, 1893, p. 1260, referring to an intestinal clamp described in THE LANCET of Sept. 30th, 1893, p. 813, by Mr. W. A. Lane, drew attention to a clamp forceps "which has a more extended application in abdominal operations." "These forceps," he wrote, "have curved, flat blades with a parallel grip and they are made of various sizes; they can be applied to the stomach, gall-bladder, cæcum, intestine, or any cyst wall. Their purpose is to occlude the cavity on the convex side of the clamp and to isolate the part included within the blades during the application of sutures, whether it is for closing a wound or for attaching the part to the abdominal wall. The blades can be sheathed with rubber tubing or used naked." Doyen, whose forceps Mr. Littlewood used, described his *pince à mors élastique* and illustrated their use in stomach surgery in his work, "Traitement Chirurgical des Affections de l'Estomac et du Duodenum," in 1895 (pp. 294, 302, and 303). These references will, I think, suffice to show that the use of clamps was of much older date than 1900 and that Mr. Littlewood has no claim to priority in their use either in stomach or intestinal work. If Mr. Ward had been content to claim for Mr. Littlewood that he used the clamps before any other surgeon in Leeds I should have agreed with him entirely, as I have previously told Mr. Littlewood there can be no doubt whatever about that.

The second point is concerned with the question of the excision of the mucous membrane in anastomotic operations. Mr. Littlewood considered this, as the title of his paper shows, an essential and original part of his procedure. The paper which Mr. Littlewood read was published in THE LANCET of June 29th, 1901, p. 1817. My publication of a paper read before the Mirfield Medical Society appeared in the *British Medical Journal* of Dec. 8th, 1900, p. 1631. In that paper I wrote: "An incision two inches to two and a half inches long is made through the serous and submucous coats only; as they are divided they retract and an ellipse of mucous membrane over half an inch wide in the centre and narrowing off at each end pouts into the wound. Two pairs of nibbed forceps, one towards each end, grip and pull upon the ellipse of mucous membrane, which is then excised."

When Mr. Littlewood read his paper in Leeds I joined in the discussion. He will, I think, remember that I then said I had practised the excision of the mucosa in the way I have described and in my remarks I attributed my thought of this procedure to the "stamping out" process of the Murphy button, which removes a portion of the apposed viscera and so forms an opening in place of a slit. I have, in conversation, since told Mr. Littlewood that I believed that in this matter the priority rested with me. In the first edition of "Diseases of the Stomach," written by Mr. Mayo Robson and myself, I devoted a paragraph (p. 273) to the question of the removal of the mucous membrane in gastro-enterostomy. I put my own opinion and practice first and Mr. Littlewood's second, because I thought then that this was the order of precedence. In later papers I have not hesitated to describe this procedure as due to my own thought and as owing its origin, in my own mind, to the use of the Murphy button.[2] Obviously, then, when this claim for Mr Littlewood's priority is made it is a question of ascertainable fact which is at stake; it is not a question of opinion.

The evidence I offer is this. The first occasion upon which I performed the excision of the mucosa was on June 1st, 1900,[3] the second was on June 6th, 1900, a patient of Dr. H. J. Clarke of Doncaster. This case is not included with the one just named because at the time I believed the condition to be malignant. It is, however, included in my "Report" to the British Medical Association last July, a copy of which I sent to THE LANCET (p. 87)[4] I have changed the case from the "malignant" to the "simple" series, because the patient is alive and in perfect health at the present moment. The third case was on August 1st, 1900.[5] These cases have been on record unchallenged now for over five years and during that time I have repeatedly expressed my belief that this procedure was original in my own mind. Mr. Littlewood has not published any dates of operations performed either in the paper to which Mr. Ward refers or subsequently. It remains with him or with Mr. Ward to put forward now the date of his first operation.

[5] See also Brit.

This, then, is my reply to Mr. Ward: First, so far as concerns the clamp. Mr. Littlewood has never given a written hint to the effect that he considers himself to be introducing a new method into the technique of intestinal suture. Had he made any claim to authorship in this matter it could not, in my judgment, and by reason of the evidence I have submitted, with himself as one of the witnesses, have been sustained. If Mr. Ward now makes such a claim for him I shall be interested to hear by what arguments he proposes to establish it. But whether Mr. Littlewood's precedence is or is not asserted is immaterial so far as I am concerned, for neither verbally nor in writing, directly or by implication, have I ever put forward a claim for myself. I hope I make myself quite plain to Mr. Ward. What I have been able to do in the matter of the use of clamps is accurately stated by Dr. Mayo, who says that I have "popularised" them. That I hope and believe to be true. *Secondly*, so far as concerns the excision of the mucosa, I have from the first and always claimed this as a procedure original with myself. Mr. Littlewood himself cannot, I think, be in any doubt about my opinion. The facts upon which my opinion is based have been published in every relevant detail for five years. If there has been "omission" or "inadvertence" it cannot, I think, be justly imputed to me.

Mr. Ward in his wonder as to the details of the method to which Dr. Mayo attached my name shows that he has not done me the honour of reading the description of the operation of gastro enterostomy (as I then performed it) which I read before the American Surgical Association in 1903. In two "essential features" I have altered the operation since then. What I now consider them will be seen by reference to pp. 157 and 158 of my book on "Abdominal Operations." I give there eight chief points and the only one common to the operation as I practise it, and Mr. Littlewood's method described in the paper to which Mr. Ward refers, is the excision of the mucosa. In the operation as I practise it to-day there are many "essential points" (as I consider them); some may possibly be original, many may be adopted from one surgeon or another, but the complete procedure is a *different operation from* any with which the literature of the subject makes me acquainted.

I am, Sirs, yours faithfully,
Leeds, May 14th, 1906. B. G. A. MOYNIHAN.

THE EMPLOYERS' LIABILITY BILL AND PRACTITIONERS IN MEDICINE.

To the Editors of THE LANCET.

SIRS,—Now that the above Bill is before Parliament I would suggest that the different divisions and branches of the British Medical Association and other medical societies take immediate action so that all medical practitioners shall be included in the above Bill. Almost all the illnesses and accidents which attack us come through our dangerous occupation, while each year finds the majority less able financially to provide against sickness, accidents, infirmity, and old age.

I am, Sirs, yours faithfully,
Liverpool, May 15th, 1906. ROBERT R. RENTOUL.

DEATHS UNDER ETHYL CHLORIDE.

To the Editors of THE LANCET.

SIRS,—In reference to the death under ethyl chloride reported in THE LANCET of May 5th, 1906, p. 1236, Case 10, by Dr. T. D. Luke, as having occurred at this institution, on page 1236 it is stated that "the administrator was a student who had practically no experience of anæsthetics and the operator was a house surgeon who had performed this operation only on half a dozen previous occasions." Both these statements are incorrect. The anæsthetic was given by the assistant house surgeon who was fully qualified and I was the operator. I have performed this operation very many times, as many, I venture to say, as Dr. Luke has administered ethyl chloride, not half a dozen as stated. I think Dr. Luke should have ascertained the correct facts before publishing any which, if true, would reflect not only on this institution but on myself. As the matter stands it shows a deplorable want of care in the collection of the facts and reflects on the veracity of other statements.

I am, Sirs, yours faithfully,
THOMAS YOUNG SIMPSON,
M.D., B.S. Durh, M.R.C.S. Eng., L.R.C.P. Lond.
Royal Albert Hospital, Devonport, May 14th, 1906.

PELLAGRA NEAR MILAN.

(FROM A CORRESPONDENT.)

THE LANCET is kept well informed of the efforts of the Italian Government, aided by many benevolent societies, to fight the disease which is caused by eating bad maize, or that cereal insufficiently dried or ill preserved. In discussing this question it cannot be too often observed that healthy maize does not produce pellagra, for the dreaded disease is apparently caused by one or more moulds present in the corn, the toxic spores chiefly suspected being the aspergillus *fumigatus* and the *penicillum glaucum*. The aspergillus occurs chiefly during the warm months in Italy and seems to be the more important of the two, for though in a test-tube it is killed at 100° C., it is found to live for at least 25 minutes at 85° to 90° C., which is probably quite as high a temperature as that of any oven used by the Italian peasants for baking their bread. Their bread consists of a mixture of maize flour, 16 per cent., and rye flour, 84 per cent. The Italian law of 1902 makes pellagra a notifiable disease; it prohibits the sale of bad maize; and it makes compulsory on the local authorities the construction of drying houses for maize and the treatment and maintenance of pellagrous patients in their homes and in special retreats; the expenses are partly borne by the central Government. But, like many other things in Italy, it is to be feared that these regulations, so excellent on paper, are not very thoroughly carried into practice. I can, however, vouch for the utility of one of the chief retreats—that for the province of Milan at Inzago which I lately had the pleasure of visiting with the enthusiastic director, Dr. G. Friz, who has devoted some 30 years to the consideration of pellagra and to attempting to improve the condition of the poorer peasants. The retreat is built in the midst of agricultural fields, for the accommodation of some 50 young people aged from 12 to 24 years, most of whom are children of pellagrous parents and have already shown the first signs of the disease. The early symptoms discovered are usually giddiness, stupidity, depression of spirits, general debility, loss of appetite, a feeling of burning or of fulness at the epigastrium, diarrhœa and erythema or dry desquamating skin on the dorsum of the hands and feet or at the neck. The retreat has been constantly used since it was founded in 1890, since when about 1200 boys and girls have undergone a six months' treatment, for each sex is treated in turn. The average gain in weight is from four to 26 pounds during the six months, which shows that the rations are good. The diet is varied and once a week they are allowed to have maize flour in their favourite *polenta*. They are taught by some devoted sisters of mercy with the result that whereas only 6 per cent. can read and write on admission 42 per cent. have acquired these arts before leaving. Every day they have one hour's lecture on elementary personal hygiene and the rest of the day is spent in work out of doors. The boys till the fields round the house and are specially taught why bad seed should not be planted, and why cereals must not be harvested unripe, and must be well dried and then kept dry. The girls are taught sewing and knitting and everything relating to silkworms and their successful development, including some knowledge of the mulberry tree, which is so common in that district. Dr. Friz also visits the homes of the young people in order to see whether the parents are really poor and to keep an eye on the patients who have passed through his hands.

The number of peasants in Milan province now affected by pellagra is said to be 12 per 1000, while at Bergamo the number is 20 per 1000. It is interesting to remember that the first hospital for the treatment of pellagra was opened in 1784 at Legnano under the auspices of the Council of the Duchy of Milan. The total number of pellagrous cases in Italy is now said to be 72,000.

I took the opportunity while in this neighbourhood of renewing my acquaintance with the County Lunatic Asylum of Milan at Monbello. There were 857 admissions during last year and the number of patients remaining on Jan. 1st, 1906, was 1383, the two sexes being almost equally divided. The total number of pellagrous admissions during last year is entered in the report as 62, but that cannot in any way represent the number of lunatics who are pellagrous, for in every courtyard I found at least a dozen pellagrous lunatics. The deaths from pellagra during the year were 13 men and 22 women. At this spring time of the year the erythema can be very well seen on the exposed parts of the body. This asylum is now under the direction of Dr. G. B. Verga, the nephew of a professor whose name is well known in pellagra literature, and he is aided by ten assistants, one of whom, Dr. Rossi, is doing some excellent microscopic work.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The New Pathological Department of the University.

ALTHOUGH a certain number of details have yet to be dealt with the new pathological department is practically complete and work has commenced in it. The new department may be entered either through the old pathological department, which is still retained for histological classes, or by a special entrance in the new buildings. In the basement are the animal rooms, the operating room, the mortuary, a centrifuge room, and a projection room and associated dark room. On the ground floor, to the left of the main entrance, is the assistants' room, and to the right is the private room of the special demonstrator for public health work. At the back on this floor is a beautifully lighted and splendidly fitted bacteriological class-room from which there is access to the histological laboratory. In addition there is a room which will be devoted chiefly to kymographic work. On the second floor are the private rooms of the professor and the demonstrator, a large clinical room, and a balance room. On the third floor are a laboratory reserved for the private use of the medical officer of health and a large research laboratory. In addition to the main rooms there are a number of smaller rooms for special research work, all admirably designed and fitted, well lighted, and well ventilated. The department is an important addition to the resources of the University and the city and it provides unsurpassed facilities both for teaching and for research.

Playgrounds for City Children.

It is well known that the healthiness of town districts depends very much upon the plentifulness and freedom of their air-supply. Apparently the conditions in Birmingham as regards air-supply and open spaces are very unsatisfactory, for Dr. J. Robertson, our medical officer of health, who has been making investigations upon the subject, points out that when public parks and other open spaces are taken into account Birmingham is in a worse position than other manufacturing towns of this country. Taking eight of the largest manufacturing towns—Newcastle, Bradford, Bristol, Manchester, Nottingham, Liverpool, Sheffield, and Birmingham—the number of people per acre of park and open space increases from 206 in the case of Newcastle to 1026 in Birmingham. Birmingham is unfortunate also in the fact that the areas to the south, north, and north-west of the city are built upon and densely populated, and the air coming to us from them is therefore more or less deteriorated as contrasted with that which reaches some of the more favourably situated cities. Moreover, we have no large river passing through our midst to sweep in fresh air with the flow of its stream. Dr. Robertson finds that in many of our central districts the only places in which the children can play are inclosed and in some cases unwholesome courtyards and it is not possible for the children to get to satisfactory open spaces where there are trees and shrubs. It is, of course, impossible, on account of expense, to provide parks in these central districts but it is occasionally possible to acquire small areas which can be opened up and transformed into wholesome playgrounds which will serve also to increase the air-supply of the surrounding buildings. Opportunities of this kind, however, are allowed to slip by because it is no one's duty to take advantage of them and to obviate this it is proposed to form a committee to promote the formation of an association the members of which will unite in an attempt to provide the central districts with as many open playing spaces as possible. Besides the medical officer of health, Councillor Nettlefold, Professor Muirhead, Professor Ashley, and Mr. Kirkaldy are taking a prominent part in the movement. It is to be hoped in the interests of the city's health that a powerful association will be formed and that the object desired will be attained.

The Health of the City.

During the last three weeks the death-rate of the city has fallen steadily from 21·4 per 1000 to 16·9 per 1000. Deaths from most of the zymotic diseases have decreased, but for a brief period there was a decided rise in the notifications of scarlet fever. This, however, was merely a passing fluctuation from which there was a prompt recoil and there is obviously no reason to fear an epidemic.

Canal-boat Life.

In THE LANCET of April 7th I drew attention to the difficulty which Dr. J. D. McCrindle (assistant medical officer of health) had experienced in getting information regarding the deaths of children born on canal boats. A lurid side-light has been thrown on this matter during a recent investigation in the Wolverhampton coroner's court into the cause of death of a child three weeks old. The mother stated that the child was prematurely born and that she had had 15 children, nine of whom had died in infancy. She added that she worked on the boat to within a short period of each birth. It was asserted at the same inquiry that two cases were known in one of which only one child out of 14 survived and in the other all the eight children born died in infancy. The coroner commented strongly on the matter and expressed the hope that some action would be taken to prevent women working at such critical periods of life.

May 15th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool School of Tropical Medicine.

THE King of the Belgians has sent to Sir Alfred Jones, the chairman of the School of Tropical Medicine, a letter intimating a contribution of £2600 to the funds of the school. This sum is in addition to the large amount which King Leopold has already contributed to the school. Sir Alfred Jones has also received a letter in the following terms from the Secretary-General of the Congo Free State in Brussels: "Referring to our recent conversation, I beg to confirm to you that the Government of the Congo Free State has resolved to bear the expense which was occasioned by the visit of the members of the Liverpool School of Tropical Medicine during their sojourn in the Congo. These expenses, which include in a general way the maintenance of the expedition, the salaries of the attendants, and transport expenses, amount to £1421. The Government desires by this decision to show its sympathy with the philanthropic work undertaken by the School of Tropical Medicine and with the spirit in which its members acquitted themselves in their mission to the Congo." Dr. Jacques of Brussels has been deputed by the King of the Belgians to attend the course of instruction under the auspices of the Liverpool School of Tropical Medicine.

Joint Matriculation Board of the Universities of Liverpool, Manchester, Leeds, and Sheffield.

The arrangement whereby the matriculation examination can be held in July at a school as a form examination under the ordinary regulations requiring candidates to offer five subjects and not allowing them to offer more has been extended to meet the case of schools in which the curriculum demands six subjects. In such a case a form will be allowed to take six subjects provided that either Latin or Greek is included among them. In order to obtain a matriculation certificate a candidate must satisfy the examiners in the two obligatory subjects and in three of the optional subjects, one of the three subjects being a language.

The High Death-rate of Liverpool.

At the weekly meeting of the health committee of the city council held on May 10th the chairman referred to the high death-rate, which during the past week was 27 per 1000, and said he thought that it was only right that something should be done to diminish it. The chief causes of the increased rate were old age, the weather, the epidemic of measles, and infantile mortality. He suggested that the medical officer of health (Dr. E. W. Hope) should prepare a comparative statement of the death-rates in the different districts and submit it to the committee which could then consider the steps to be taken in those districts where the highest death-rate occurred. Crewe appears to be in a much more fortunate condition than Liverpool, as in the former town the death-rate during the month of April reached the remarkably low figure of 8 per 1000, establishing a record in its history. The medical officer of health (Dr. A. J. Laird) in his weekly report states that this happy result is due to the comparative freedom from infectious disease among children and to the low infantile mortality.

Cheshire New Nursing Association.

A large and influential meeting, convened by the Duke of Westminster, was held on May 5th in the council chamber of Chester town hall to consider the advisability of forming a county nursing association for Cheshire. The Duke of Westminster presided and the attendance included the Earl of Crewe, the Bishop of Chester, Lord and Lady Stanley of Alderley, Sir John Brunner, Bart., M.P., and others. The association maintains a nurse who visits the districts, reports to the local committees, and gives help and advice when required. It also keeps a reserve of two or three nurses available as substitutes. The Duke of Westminster explained that some time ago it was suggested to him that it would be desirable to convene a meeting of those interested in the county for the purpose of starting a county nursing association. There were many local nurses employed in Cheshire, but the local committees acted independently and it was with the idea of bringing those local committees together that they hoped to justify the existence of a county nursing association. Influential support had already been promised but he would like to lay stress upon the fact that that was not a scheme which should merely be supported by influential people but that it should be maintained by the help of the whole county. Miss Hughes, general superintendent of the Queen's Institute, gave an interesting address on the work of the county associations, pointing out their great advantages. The Earl of Crewe moved:—

> That a county nursing association for the county of Chester be formed, this meeting fully recognising the advantage of forming such an association.

He said that scientific nursing had only really moved during the last 50 years and it had always been associated with the name of Miss Florence Nightingale. He alluded to the admirable work done by the Queen's Jubilee nurses. The Bishop of Chester seconded the motion which was unanimously carried. The Duke of Westminster was elected president, and the list of vice-presidents included the Duchess of Westminster, Katherine, Duchess of Westminster, the Earl and Countess of Crewe, the Earl and Countess of Stamford, the Bishop of Chester, Lord and Lady Newton, Lady Stanley of Alderley, Mrs. Henry Gladstone, Sir John Brunner, and others.

May 15th.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Bristol Lunatic Asylum.

THE visiting committee of the Bristol Lunatic Asylum at Fishponds in its forty-ninth annual report, which has just been issued, states that on Dec. 31st, 1905, the number of inmates in the institution was 944 (418 males and 526 females). The highest number in residence at any period during the year was 957. Plans providing for further accommodation for 59 male patients have obtained the approval of the Commissioners in Lunacy and the work will shortly be commenced. The committee adds that it has reduced the weekly charge of maintenance from 11*s*. to 10*s*. 6*d*., and in conclusion records its appreciation of the way in which the duties connected with the institution have been performed by the medical superintendent (Dr. J. V. Blachford) and staff.

The Somerset Education Committee and Medical Certificates.

At a meeting of the Somerset education committee held at Bridgwater on May 8th the school attendance committee reported that as the medical practitioners of the Taunton rural district did not approve of the county committee's scale of fees they refused to grant medical certificates in cases of absence from school through alleged illness and the district sub-committee had accordingly been instructed not to ask for medical certificates.

Vaccination at Stonehouse.

At a meeting of the Stonehouse board of guardians held on May 10th a discussion took place concerning the cost of vaccination. It was stated that the vaccination fees for the past quarter were £48, compared with £24 for the corresponding quarter of 1905. The clerk said that the increase of expenditure was due to the present small-pox scare.

District Nurses for the Poor at Plymouth.

A scheme has been initiated by Countess Fortescue, wife of the Lord-Lieutenant of Devon, and the Earl of Mount Edgcumbe with a view to provide nurses for the poor of the "Three Towns" and eventually to establish a training home similar to the institution at Plaistow. An influential committee has been appointed and £250 have been already promised. It is intended to affiliate the branch with the Devon County Nursing Association and with the Queen Victoria's Jubilee Institute for Nurses. At an early date a public announcement will be made of the scheme with an appeal for financial help.

May 14th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Scottish Poor-law Medical Officers.

LAST week a deputation waited upon the Secretary for Scotland with reference to the position of the Poor-law medical officers in Scotland. Mr. W. L. Muir of Glasgow, the secretary of the Scottish Poor-law Medical Officers' Association, stated the case for the deputation and drew attention to several grievances which they wished to see remedied by legislation. First, they desired to have an application to the Local Government Board in cases of unjust dismissal by the parish council, there being, as they contended, many cases in which that power was harshly and unreasonably exercised. They pointed out that in some remote districts dismissal might mean absolute ruin to the medical officer. In the second place, they claimed to have a right to order an invalid diet for paupers without an appeal to the inspector of poor who had at present the power to veto any special diet which they prescribed. Thirdly, they urged that powers should be given to erect from parochial funds dwelling-houses for medical officers, there being many parishes in which they could not obtain proper accommodation. In the fourth place, they contended that they should be granted a suitable annual holiday when the greater part of their income was derived from parish sources. (At present they could not obtain a holiday without paying four guineas a week for a locum tenens.) Fifthly, they urged that a uniform fee of one guinea should be given for granting a lunacy certificate. At present there was a great diversity in the fees that might be paid by the parish council for those cases and in many instances the medical man got nothing at all. They also urged that there should be a special fee for special cases which they had to attend. In substance, they asked that they should be put in the same position as the Poor-law officers in England and Ireland. Their education and duties were the same and their status ought to be made at least as satisfactory. They further suggested that there should be a special Government subvention for the outlying islands and poorer parts of the Highlands. The Secretary for Scotland promised to make full inquiry into their complaints.

Lodging-houses on Fire.

A series of regulations has been drawn up by the special committee appointed by the corporation of Glasgow to report upon the disastrous fire which occurred some months ago in a model lodging-house in the city and which resulted in the loss of so many lives. The regulations will commend themselves to everyone who has realised the possibility of fire in these crowded lodging-houses. The provision, in particular, that every lodging-house or hotel with sleeping accommodation for over 100 persons should have at least two adequate means of exit to the street is a wise proposal, though it may cause some inconvenience and expense to the proprietors. It may not prevent fire but it will at least minimise the consequences of a serious outbreak so far as loss of life is concerned. The prohibition of smoking and the use of lighted matches or candles in the dormitories is also, no doubt, a wise precaution but it remains to be seen whether this will be able to be enforced rigorously.

Port Glasgow's Insanitary Central Area.

The medical officer of health of the borough of Port Glasgow, in submitting his annual report, states that much of the disease in Port Glasgow is due to the insanitary housing of the poorer classes. Writing of the central area of the town, he says that the whole of this area is an unhealthy area within the meaning of the Housing of the Working Classes Act. Within that area nuisances abound. The principal and most apparent nuisance arises from the lack of water-closet accommodation. Lacking that, the "ashbins" become unspeakably filthy. He quotes sections of the Burgh Police Act which empowers the local authorities to require the introduction of water and a jawbox into each house in some window recess or other well-lighted place, and points out that if this provision alone were enforced in the central area of Port Glasgow it would bring about a sanitary revolution there.

Crusade against Consumption.

For some time past the authorities in the larger towns of Scotland have been making efforts to stamp out, or at least to control, the spread of consumption in their midst. It is with considerable gratification that the smaller towns are attending to their responsibility in this matter within their own borders. The public health department of Greenock has agreed to recommend that a system of voluntary notification of consumptive cases should be adopted; that leaflets should be issued bearing on the treatment of the disease; and that the directors of Greenock Infirmary should be approached with the view of obtaining a few beds in one of the unused wards of the hospital. Helensburgh also has decided to try voluntary notification and in the meantime the emergency hospital is to be utilised for the treatment of those suffering from this disease. It is worthy of note also that Clackmannan County Council is printing and circulating broadcast throughout the county a short treatise on consumption by the county medical officer.

May 15th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Health of Dublin.

AT the usual fortnightly meeting of the public health committee on May 1st Sir Charles Cameron, medical officer of health of the city, reported that the death-rate during the previous fortnight was 27·4 per 1000 persons living and stated that this was the lowest record since the accurate registration of deaths was commenced. It is still high, however, and among adults is largely due to enteric fever. At the last meeting of the managing committee of Cork-street Fever Hospital on May 10th the registrar reported that many cases of that disease of a very severe type had been admitted. The corporation is aroused and is now attempting to deal with the tenement house problem by building new houses for the artisan class, while an effort has been made to secure a safe supply of milk. Mr. T. J. Lawler has proposed a motion in the council, which was seconded by Dr. J. C. McWalter, and adopted, that the council should take steps:—

> To cause all consignors and consignees of milk coming into the city to be registered; to have certified that all such milk was taken from cows free from tuberculosis; that the premises in which the cows were housed were in a sanitary condition; that the premises used for storing the milk should be clean; that no infectious disease was amongst the employés concerned in the collection or storage of such milk; that the vessels used in storage and transmission of such milk were clean.

Mr. Lawler remarked that 50 per cent. of the milk used in the city of Dublin came from the country and within the past two years not so much as one pint of that milk had been examined in any way before it was used by the inhabitants. He said they had in the city over 300 dairies, which were compelled to comply with the duties imposed on them by the by-laws of the corporation, while the greater portion of the milk was supplied without any restrictions or supervision whatever. In reply to an objection as to the practical difficulty of carrying out his scheme, the proposer of the motion said that the Liverpool corporation had in force a law similar to that which he suggested that they should adopt in Dublin. The motion was carried and despite the difficulties put upon the executive the citizens of Dublin will probably be found on the side of reform. Many statements have appeared during a long period as to the number of deaths among infants in this city and the uniformly high death-rate in Dublin is affected by the infantile mortality—points which are in favour of supervising the milk-supply.

National Maternity Hospital, Holles-street, Dublin.

The monthly meeting of the board of the National Maternity Hospital was held on May 8th, the Very Reverend Canon Fricker, P.P., presiding. The governors proceeded to elect an intern assistant physician in the place of Dr. John J. O'Hare whose three years' term of office was ended. There were three candidates for the position, of whom Mr. A. Roche had a majority of votes and was elected.

The Health of Belfast.

On May 8th a conference was held in Belfast under the auspices of the "Citizens' Association" in reference to the alarmingly high death-rate in the city. The meeting was convened by circular and was representative of the various public organisations in Belfast The chairman (Mr. S. H. Woods), in opening the proceedings, pointed out that as a result of the recent discussion in the Belfast papers on the high death-rate from pulmonary tuberculosis the public had become alarmed and dissatisfied. Incidentally he paid a high compliment to Professor J. W. Byers for what he styled the "illuminating information" which he had given in his articles. Dr. W. Calwell (President of the Ulster Medical Society) brought forward the first motion:—

> That the alarmingly high death-rate of Belfast, especially from tuberculosis in its various forms, demands vigilant attention from the citizens and vigorous action by the responsible authorities, and shows the urgency and imperative necessity that the city council should secure the highest specialised professional skill and lengthened experience available in the United Kingdom for the oversight of our public health.

In support of the words "alarmingly high death-rate of Belfast" Dr. Calwell quoted a number of figures from tables which were circulated amongst the audience. In 1904 Belfast was seventy-fifth to seventy-seventh out of 82 large towns in the United Kingdom in its high death-rate, 20·9. In 1903 Belfast was seventy-seventh out of 80 large towns; in 1902 it was seventy-seventh out of 80 towns, and in 1901 it was thirty-sixth out of 37 large towns. Practically Belfast during these four years had the worst death-rate in the United Kingdom, with the exception of Dublin, Liverpool, and Wigan. The two latter cities had a higher death-rate than Belfast on two occasions and so were equal. Such figures showed that the death-rate of Belfast was "alarmingly high." Turning to pulmonary tuberculosis, Dr. Calwell showed the death-rate to be worse than in Leeds, Nottingham, Glasgow, and Liverpool, while the only form of tuberculosis mentioned in the health report of Belfast was pulmonary tuberculosis. As to zymotic diseases, with the exception of typhoid fever Belfast came fairly well out of comparison with other cities but the annual report for the last six years or so had made no mention of the increase of insanity, of cancer, of heart disease, of pneumonia, of rheumatic fever, and of alcoholism; he then referred to the very unsatisfactory nature of the health reports of Belfast in other respects. In the report for 1899 it was regretted that information was not forthcoming concerning the causes of death in 4063 cases out of 7933, the other 3870 deaths being due, 2865 to chest affections and 1005 to zymotic diseases. In the report for 1904 information was not forthcoming concerning the causes of 3700 deaths, and Dr. Calwell hoped that the corporation would appoint a specialist in public health to advise them. The motion was seconded by Mr. W. Crawford, J.P., chairman of the board of management of the Royal Victoria Hospital and carried. Mr. John Murphy (secretary of the Trades Council) then proposed the following motion:—

> That the impending resignation of the superintendent medical officer of health presents a unique opportunity to the city council for the appointment of an experienced medical officer possessed of the highest scientific knowledge and training in public health matters, and for such changes in the constitution of the health department as may be required for carrying out necessary reforms, and this conference is of opinion that the city council should take action accordingly.

This was seconded by Dr. Clarke Robinson and carried.

Finally, on the motion of Mr. G. W. Ferguson, it was decided to forward copies of these resolutions to each member of the city council and to appoint a committee to take steps on behalf of the citizens for the furtherance of the objects in view. Accordingly, upon a very influential committee of citizens of Belfast the following medical men were appointed: the chairman (Dr. Calwell) and the secretary (Dr. T. Houston), Dr. J. R. Davidson, and two others (to be appointed by them) from the Ulster Medical Society, Professor Byers, Professor T. Sinclair, Professor J. A. Lindsay, Sir William Whitla, Dr. A. Dempsey, and Dr. C. Leathem.

The Retirement of the Superintendent Medical Officer of Health of Belfast.

Dr. Henry Whitaker having resigned the position of superintendent medical officer of health of Belfast, great interest is being taken in the appointment to be made by the city council as to his successor. It having been suggested in the Belfast papers that the Citizens' Committee had a particular candidate in view, the following motion was unanimously carried at a very fully attended meeting on May 14th of the new Citizens' Health Committee appointed at the conference held on May 8th:—

> That the attention of this Citizens' Health Committee having been called to certain statements circulated and also conveyed by innuendo in the public press on Monday, the 14th inst., it is hereby resolved that this committee emphatically repudiates, both collectively and on the part of its individual members, any interest whatever in the candidature of any persons, local or otherwise, and reiterates its adherence to the principle outlined in the resolutions of the representative meeting lately held—namely, that the appointment to the office of medical superintendent officer of health should be made only by open selection from the highest specialised professional skill available in the United Kingdom.

The City Infectious Diseases Hospital, Belfast.

Mr. P. C. Cowan, inspector of the Local Government Board, held an inquiry in Belfast on May 11th with reference, *inter alia*, to an application from the corporation of Belfast to borrow £25,000 for completing and furnishing the new infectious diseases hospital at Purdysburn, Belfast, which it is hoped will be ready for opening next August.

May 15th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Changes in the Curriculum of the Paris Faculty of Medicine.

THE President of the Republic has signed a decree which has been submitted to him by the Ministers of Public Instruction and of the Interior and which will involve some modifications of the existing course of medical study. It provides, for instance, that third year students shall attend the practice of a lying-in hospital for four months and during a further period of four months in the same year shall attend one of the special departments for the treatment of diseases of the skin and syphilis, mental diseases, diseases of children, diseases of the eye, and diseases of the urinary passages. Attendance on these courses shall last from Nov. 1st to June 30th. The students shall take up the subjects in such a manner that four months may be given to medical work and four months to surgical work. The decree will come into force on Nov. 1st and the Ministers of Public Instruction and of the Interior, each of them so far as his department is concerned, will be responsible for carrying it out.

The Manual Treatment of Sciatic Neuralgia.

M. Berne is of opinion that massage almost always relieves the various neuralgias of the sciatic nerve and that when combined with certain manipulations it very often yields a successful result in obstinate cases, always provided that the disease is peripheral and neuritic in character; cases of central origin are not amenable to the treatment. When there are lameness and muscular retraction straightening of the limb may be tried. M. Berne has for the last 20 years employed what he designates as "the knee method." The sciatic nerve, passing between the posterior border of the great trochanter and the ischium, rests, as is well known, on the spine of the ischium, against which the flattened trunk of the nerve can be easily compressed after leaving the pelvis. It occurred to M. Berne that this anatomical arrangement might be made to serve a therapeutic purpose by enabling the nerve to be compressed against the adjacent bony surface and he described his procedure at a meeting of the Société de Médecine de Paris held on April 28th. Having caused the patient to lie at full length in the dorsal position on a low couch, M. Berne stands on the affected side. If the sciatica is in the right thigh M. Berne flexes his right knee and holds it firmly against the patient's right sciatic notch; he then seizes the extremity of the patient's right lower limb and flexes the thigh on the pelvis with the leg extended on the thigh. In this way he exerts gentle progressive stretching, quite free from danger, and not requiring the administration of chloroform. This method has given excellent results in old cases of sciatic neuritis occurring in patients who had derived no benefit from the ordinary and recognised forms of treatment. In the manual treatment of sciatica M. Berne is in the habit of supplementing this extension by various movements, including active and passive adduction and abduction of the affected limb, together with movements of circumduction and flexion combined with rotation of the trunk. All these manipulations are, however, of secondary importance in comparison with the prompt and effectual action of the "knee method." It is important to remember that, as already mentioned, the disease must be some form of sciatic neuritis having a peripheral origin. In reply to M. Coudray, who asked a question relative to sciatic neuralgia due to the presence of dilated veins at the point of emergence of the sciatic nerve, M. Berne said that he had seen cases of this kind, in which the pain was caused by varicose veins pressing on the nerve, but he had always declined to undertake the treatment of them because they were purely surgical cases which could only be dealt with by removing the conditions which brought about the compression.

The Cause of the Hair turning White.

This interesting question was discussed by M. Metchnikoff at a meeting of the Academy of Sciences held on May 7th. One of the explanations which have been suggested for the hair turning white is that the individual hairs become dry with age and that the air penetrating into their interior destroys their pigment. Others have said that the colouring matter of the hair of any part of the body (*des poils et des cheveux*) disappears under the influence of a chemical substance. M. Metchnikoff, however, is persuaded that the whitening of hair is a vital phenomenon due to cellular activity. Hair, according to him, is not an inert material; it is alive and is composed of living cells provided with prolongations which envelop and destroy pigmentary substances in contact with them. These "chromophagic" cells in this way gradually destroy the colouring matter of the hair and spread in each direction both towards the root of the hair and towards its extremity. This may be recognised by the fact that after the greater portion of the hair has become white the root still remains coloured. M. Metchnikoff has observed that the hair of women who use curling tongs heated to 60° or 70° C. is comparatively slow to lose its colour. The heat destroys the chromophagic cells. In order to make a scientific study of the whitening of hair M. Metchnikoff used animals whose hair is white in winter and dark in summer, and in this way he found that in some species of Russian and Alpine hares the change from dark to white follows the same course as in the human subject. Moreover, when a person's hair turns white in a single night under the influence of mental shock it is certain that the change is due to excessive excitation of the chromophagic cells which thereupon destroy the colouring matter of the hair in a few hours.

An Oceanographic Institute in Paris.

The Prince of Monaco has written to the French Minister of Public Instruction announcing that he has founded an oceanographic institute to be established in Paris. He has presented to this institute the Oceanographic Museum of Monaco, including laboratories, collections, aquariums, and whatever pertains to them, and for its support he has provided a capital sum of 4,000,000 francs. The institute will be built on the land which the University of Paris, in conjunction with the Prince, has just acquired in the Rue St. Jacques and the Rue d'Ulm. The statutes of the institute provide that its scientific work shall be under the control of an international committee (*comité de perfectionnement*), the membership of which shall be open to eminent authorities in the various departments of oceanography irrespectively of the country or nation to which they belong. The Minister of Public Instruction has directed M. Casimir-Périer to convey to the Prince the thanks of the French Government for his magnificent gift, the value of which exceeds 10,000,000 francs.

Successful Ligature of the Axillary Artery for Aneurysm.

At a meeting of the Surgical Society held on May 2nd M. Loison described a case in which a man, 27 years of age, had received a wound from a revolver bullet in the region of the left axilla. The aperture of entrance being in the side and that of exit near the spinal border of the scapula it seemed probable that the thoracic cavity had not been traversed, and this opinion was confirmed by the subsequent progress of the case. On the following day the radial pulse was quite perceptible but there was some interference with sensation and motion in the region supplied by the musculo-spiral and ulnar nerves. These symptoms did not become worse as time went on, but at the end of a month the axilla contained a tumour which had all the characters of an arterial aneurysm. On an operation being performed it was found that the whole length of the axillary artery was occupied by a pouch which could be separated from the median nerve but not from the musculo-spiral and ulnar nerves. Removal of this pouch being impossible the vessel was ligatured above and below it. The tumour eventually disappeared but there was no radial pulse, and in addition there was partial paralysis of the musculo-spiral and ulnar nerves.

The Prophylaxis of Syphilis.

At a meeting of the Academy of Medicine held on May 8th M. Metchnikoff read a paper on Some New Facts in Experimental Syphilis. After having referred to his own experiments and those of other observers on anthropoid apes and other monkeys concerning the inoculation of syphilitic matter and the production of syphilis in these animals, he mentioned that a chimpanzee, some macaques, and some baboons had been inoculated with syphilitic matter, and at varying times from one to 18½ hours after inoculation the site of inoculation had been treated with ointment containing various mercurial salts. In all the animals so treated the syphilitic virus had not produced its usual effect. These experiments were so encouraging that M. Metchnikoff determined to try the same experiment upon a human being. A student of medicine at the Faculty of Paris offered himself as a subject. He had finished his medical studies and so was fully cognisant of the object of the experiment and of the possible risk which he ran. He had never had syphilis, either hereditary or acquired. Accordingly, on Feb. 1st M. Metchnikoff, in the presence of Dr. Queyrat, Dr. Sabouraud, and Dr. Salmon, inoculated the student in the balano-preputial groove on the left side with syphilitic matter taken from a hard chancre of one month's duration, and on the right side with syphilitic virus from a hard chancre of between nine and ten days' duration. Portions of both types of virus were also inoculated into four Javanese macaques. One hour after the inoculation of the virus the inoculated parts of the student and of one macaque were rubbed for five minutes with an ointment consisting of 30 grammes of lanolin and ten grammes of calomel. 20 hours after inoculation the inoculated part of the second macaque was also rubbed with the ointment. The two other macaques were left without treatment as controls. Two days later the site of inoculation in the student showed no trace of inflammation; the marks of the scarifications were, however, obvious but even they disappeared within a day or two afterwards. On the prepuce of the student but at some distance from the site of inoculation there were two or three herpetic vesicles which disappeared in two days' time, but this was an eruption to which the patient had been subject before. No sign of syphilis had presented itself in the student, although the two control macaques developed typical syphilitic lesions, and of the two macaques which were treated with the ointment the one which was treated 20 hours after inoculation developed a primary chancre after 39 days of incubation. The one which was treated an hour after inoculation showed no sign of syphilis. M. Metchnikoff concluded by saying that this experiment is a proof that calomel ointment applied one hour after inoculation of syphilitic virus is capable of preventing the development of syphilis in man as it is in monkeys. It also proves that after 20 hours the ointment has no preventive action. He therefore has come to the conclusion that it is fair to state that calomel ointment can be utilised in the prophylaxis of syphilis. He allowed, however, that the experiment upon the student was not absolutely complete, for the control experiment which would consist in inoculating syphilitic virus without being followed by local frictions with mercury ointment had not been carried out, but he would mention that he himself had been scratched (*griffé*) by a syphilitic monkey. He had immediately rubbed the place with calomel ointment and had sustained no damage.

BERLIN.

(FROM OUR OWN CORRESPONDENT.)

Statistics of the Sick Clubs.

STATISTICAL returns relative to the sick clubs established under the workmen's insurance laws have been recently published by the Imperial Statistical Office. These figures show that in 1903 the total number of members was about 10,000,000, as compared with 4,250,000 in 1885. It must be remembered that membership is compulsory for workmen engaged in industrial employments, but not for agricultural labourers, so that the enormous increase in the number of members shows the development of industrial pursuits in Germany during the past 20 years. As a rule, though not always, the clubs are constituted so that in small places there is only one club for workers of all trades, whilst in the greater towns every trade or branch of industry has its own club and even in the case of certain great factories separate clubs exist for their workmen. Apart from these local clubs there are free clubs the members of which are spread throughout Germany. These free clubs are supported and administered by the workmen alone, whilst in the others the employers have to pay one-third of the contribution and therefore take part in the administration. The clubs differ very much in the number of their members. The largest club is one in Leipsic containing 136,000 members, so that every fourth inhabitant of the city and suburbs belongs to that immense club which includes every trade. Of the other large clubs there is one in Dresden with 90,000 members, one in Berlin with 72,000 members, and one in Frankfort with 68,000 members. There are also a great many clubs each of which has only a very few members. 1244 clubs have less than 50 members each and 2676 clubs have only from 50 to 100 members. With respect to the sick-rate, the statistics are unfortunately incomplete because the clubs only take note of those cases in which the members are unable to work and therefore are supported either by grants of money or by paying hospital fees for them. Members who have only required medical help for slight ailments without ceasing to work are not registered as sick. Of each 100 male members, 37·5 were registered as sick, whereas of each 100 female members only 32·1 were so registered. This difference between the sick-rate of the sexes is declared by the Office to be caused by the greater average age of the male workmen. The duration of the illness was 17·4 days on an average and the mortality, which has considerably decreased of recent years, was 0·8 per cent In 1903 on an average 3·99 marks were paid for every member for medical treatment, while in 1888 the corresponding amount was only 2·32 marks. The expenses for medical aid, medicine, hospital treatment, maintenance, &c., in 1903 were 180,000,000 marks, being 17·69 marks for every member. The sick clubs form only one part of the provision made for sick workmen; there are also, as has been explained in these columns, other institutions for sick and injured workmen, administered by other bodies and according to other principles though under the same law. It is proposed to amalgamate all the different institutions into great local bodies dealing with the whole insurance business under the workmen's insurance laws. The Minister of the Interior lately stated in Parliament that a Bill to effect that amalgamation would be introduced in about two years.

The Conveyance of Sick and Helpless Passengers on Railways.

Railway travelling in Germany for certain classes of sick and helpless persons has up to the present time been so expensive that only the wealthy could afford it. For the use of such passengers there are provided a number of special carriages which can be engaged on payment of 12 first-class fares. They are, of course, luxuriously furnished and in addition to the compartment for the patient they contain a pharmacy and compartments for a medical man, nurses, and the friends of the patient. Recently the Prussian state railways have adopted a new scheme for the conveyance of invalids at a relatively small cost, so that railway travelling is now possible for patients of moderate means. The principal feature of the system is that ordinary third-class railway carriages may be adapted for the use of invalids within 15 minutes by removing the partition which separates two compartments and thereby increasing the space available for the patient and his friends. To allow the litter with the patient to be brought into the carriage the latter is provided with folding doors and contains some material for use by the nurse in a special case. There are 60 carriages of this kind which, when not required for their special purpose, run as ordinary carriages for the conveyance of passengers. If a carriage is ordered by the public for the transport of an invalid it is sent to the station indicated, where two compartments are at once adapted for the use of an invalid, whilst the other compartments continue to be used for ordinary passengers. The amount charged is not heavy, being the equivalent of four third-class fares. A good many litters are also kept in the railway stations for the use of the public in the removal of patients from the stations to hospitals or dwelling houses and *vice versâ* at moderate charges. These litters may be placed in any third-class carriage on the condition that two tickets are taken.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

The Close of the Sixth International Congress of Criminal Anthropology.

THE scantiness of the representation of the English-speaking world at this Congress evoked some remark from the delegates of other nationalities, remembering (as not a few of them did) the contributions made by British medical men to criminal anthropology when the subject was still (so to speak) knocking at the door of modern science and pleading for recognition. Certainly, at Professor Lombroso's *séance* at the "Carceri Giudiziarii" of Turin and again at the "Casa Benefica dei Giovani Derelitti," where he illustrated the several criminal types by living "object lessons" drawn from their inmates, it was felt that in some measure he was retraversing ground occupied 60 years ago by Dr. Bruce Thomson of the Perth penitentiary; just as, a little before his most interesting exposition, Signor Enrico Ferri's lecture on "Selvaggi e Delinquenti" (Savages and Delinquents), in which striking analyses were given of "Macbeth as the criminal-né, Hamlet as the mad delinquent, and Othello as the criminal of passion," was found to be little more than a supplement to the late Dr. J. C. Bucknill's studies in the medico-psychology of Shakespeare or to the late Professor Hughes Bennett's physiological commentary on *Macbeth*. Successors of those physicians, Scottish and English, might have been heard with advantage in the discussions that followed these Italian expositions if only to indicate that the British pioneers of criminal anthropology in the nineteenth century were *not without* adequate successors in the twentieth. At the next triennial Congress of the "youngest of the sciences" it is hoped that the British Isles and colonies as well as the United States of America will be represented in a manner worthy of themselves and of the subject matter. *Au reste*, the accessory features of this last Congress were such as might well have interested the English speaking participant, from the "Esposizione" of the "armamentarium" and the "bric-à-brac" of criminal anthropology already described,[1] to the "gita di piacere" (pleasure trip) in the Val d'Aosta which formed "the last scene of all." Starting some 200 strong, on a beautiful May morning, by the train leaving Turin at 7.40 the company alighted at such spots of picturesque and historical interest as Ivrea and Hône-Bard, Verrès, and the Castello d'Issogne, at all of which the *ciceroni* of the party gave clear and succinct information as to the *memorabilia* of each. Arrived at Aosta, the "Congressisti" were entertained at a sumptuous banquet in the Hôtel de Ville by the Municipio, after which began the programme of the day, Signor Guglielmo Ferrero, the historian of Rome, leading off with a lucid and lively description in the French language of the objects of interest, the Porta Romana, the triumphal arch in honour of the Emperor Augustus (from whom the town takes its name), the amphitheatre, and other monuments of the past. Visits were also made to the Collegiata di Sant' Orso, to the cathedral, and to various points, at which Signor Casalegno of the local Alpine Club drew attention to those features of the valley and the dominating mountain peaks which endear it to the artist, the nature-student, and the poet. Contemplating the snow-fields, the wooded hillsides verdant from the "eternal April" of the torrent, and the alternation of rugged rocks and green pastures of the chamois, one was haunted by the noble lines of the Cambridge scholar, man of letters, and poet of the "Elegy," Thomas Gray:—

> "Praesentiorem et conspicimus Deum
> Per invias rupes, fera per juga,
> Clivosque praeruptos, sonantes
> Inter aquas, nemorumque noctem."

Tearing themselves away from the scene, the "Congressisti" re-assembled at 6.30 P.M. in the "Politeama Bieler" to find themselves seated at a banquet of 250 "coperti" (covers), the symposium concluding with a toast list which brought the delegates of the various nationalities to their feet in proposing or in replying to the "brindisi" (healths), all of which were honoured in the "bottled sunshine" of the country. The syndic, the Cavaliere Charrez, led off with an eloquent speech, winding up with a call, heartily complied with, to drink the health of Professor Lombroso, who thereupon made a no less eloquent reply. Many other toasts followed, all of them conceived and acknowledged in the spirit of "fratellanza" proper to the republic of science, until at 8 P.M. the company rose to catch the train to Turin, delighted at the genial *finale* to an exceptionally brilliant Congress.

EGYPT.

(FROM OUR OWN CORRESPONDENT.)

Public Health Department and Personnel.

THE sanitary department has now changed its name to this new title, chiefly because public health is a better translation of the Arabic and French names constantly in use. Sir Horace H. Pinching, K.C.M.G., and Dr. W. P. G. Graham are at the head of this branch of the Egyptian Government, while three inspectors—Major C. Garner, R.A.M.C., Mr. J. Garner, and Dr. C. Goodman—divide Upper and Lower Egypt between them. Under them there are four junior inspectors—Dr. Granville, Dr. C. C. Forrester, Mr. C. M. Ekins, and Dr. P. G. S. Williams; while at present there are two temporary inspectors added to the number. An extra bacteriological assistant has been granted for work in the Hygienic Institute. Mr. E. H. Ross has succeeded Dr. A. Baker as medical officer of health at Port Said and Dr. W. C. Hayward is temporarily replacing Mr. W. B. Orme at the hospital there. In Alexandria Dr. W. A. Betts has recently been appointed in charge of the native hospital, vice Dr. Schiess Pasha, who has retired on full pay with the rank of consulting medical officer.

Hydrophobia.

Until 1899 all patients bitten by mad or suspected animals were obliged to proceed to Paris or Athens for preventive treatment, but in that year the Italian Benevolent Society established an antirabic institute in Cairo under the direction of Dr. Tonin which has done much valuable philanthropic work for Europeans and natives alike. But the alarming increase of rabid animals has now compelled the Government to take the matter into its own hands and a new institute has been erected near the offices of the Public Health Department. This building will be ready in a few days and to it suspected patients from the Government hospital and elsewhere will now be sent, while the Italian institute will be closed. The number of individuals bitten has steadily gone up from 106 in 1902 to 423 in 1904, and reached 730 in 1905 In the last year 631 were natives, 54 were Greeks, five were British, besides two Maltese, while the rest of the patients were provided by the Italian, French, German, and Austrian colonies. It must here be explained that for some years the Government has caused every bitten person, provided he is willing, to be sent to Cairo for treatment, without waiting for an opinion as whether the biting animal was rabid or not; preventive inoculation is at once begun and is continued for the usual time unless it is definitely established by experimental inoculation that the animal was not mad. Out of the 730 men, women, and children bitten last year it is believed that the animal was not rabid in 549 of the cases. Ten of the patients died from hydrophobia while the intensive treatment was being carried out and five others died during the fortnight which followed the injection period but only one person died after this date. As is usually the case, 12 of the deaths occurred after severe bites on the face, nearly all caused by wolves, while the remaining four deaths occurred after bites on the uncovered parts of the body, and not one death occurred in those people who were bitten through their clothing. The biting animals during the year consisted of 473 dogs, 16 wolves, 3 jackals, 13 cats, 3 donkeys, 3 horses, 1 mule, 2 camels, 2 monkeys, and 1 hydrophobic human being. The wolf bites are sometimes very severe, especially about the face and head, and on one occasion a patient had to have laparotomy performed because the wounds had penetrated the abdominal wall; one wolf seriously bit 36 persons before it was killed, most of whom were children. The Government has been very tardy in compelling preventive measures in Egypt but now in Cairo and Alexandria there are trained policemen who capture stray dogs and convey them in special carts to a lethal chamber and I am told that 1500 homeless dogs have been killed since December in Cairo alone. It is intended to introduce a similar staff of police into Mansura and Port Said very soon but nothing is as yet done for the smaller towns and villages where pariah dogs are allowed to multiply unchecked. No attempt has ever been made to destroy the wolves which are even more dangerous than dogs and which occasionally attack the women and children outside the villages in the early morning while they are obeying the calls of nature. It should perhaps be explained that the wolf here mentioned, often seen and occasionally hunted by English fox-hunters in the neighbourhood of Cairo, is not the true wolf (*canis lupus*), which is apparently absent from the African continent. It is, however, quite distinct from the jackal (*canis aureus*) and is probably the animal described as the Kaberu or Abyssinian wolf (*canis Simensis*), which takes its Latin name from the district of Simen in Abyssinia where the first specimen brought to Europe was obtained. It is about as large as a big sheep dog, with a long, narrow snout, and its general colour is a pale reddish brown with a tinge of yellow, but when it inhabits the desert near the Pyramids its colour becomes modified to the prevailing sand hue. This animal, like the jackal, never appears to attack man when in health and it may be assumed that almost every "wolf" bite is the result of rabies. On one occasion a wolf actually pursued an Egyptian boy into the kitchen of a large house and bit him there severely. The boy died from hydrophobia though the treatment was begun the day after he was bitten.

---

[1] THE LANCET, May 5th, 1906, p. 1225.

Plague.

At the present time there are a few sporadic cases of plague in Deshna, Beni Suef, Minia, Kena, Behara, and Menoufia provinces, while it is reported that the rats are dying in considerable numbers at Port Said, so that a recrudescence of the disease there may occur. The public health inspectors all now believe in the disease being often conveyed by rats and they therefore take every means of destroying them. One of the successful anti-plague measures in Alexandria has been to disinfect thoroughly before the plague season begins those houses where plague has been present on former occasions. During the past year there were only 266 cases of this disease throughout the whole of Egypt, as compared with 855 cases in 1904; the deaths, too, fell from 501 to 181. This is the time of year when a fresh outbreak may at any time be heard of but the chief energies of the public health inspectors are still being concentrated on this one danger so that no great epidemic need be expected.

Cairo, April 26th.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

The Life Insurance Scandals and the Medical Fees for Insurance.

THE long-continued agitation in life insurance circles in New York has had, as far as medical examiners are concerned, a wholly unexpected result. The very general newspaper agitation in all parts of the United States resulted in an inquiry held in this city under the Armstrong Act. The committee of investigation, presided over by a well-known member of the legal profession, was assisted by members of his profession, life insurance actuaries, and others. The committee sat for nearly two months and many of the sensational details were published day by day. Finally, the committee drafted a number of laws, some of a remedial and others of a very radical curative character. These, duly submitted to the authorities in Albany, the State capital, where they passed both Houses, were approved by the Governor and will become operative at an early date. The three big companies, no less than the other American companies whose methods have not been impeached, are said to be perfectly solvent and a new era of economy is inaugurated. But the services of medical men are hardly properly recognised. The past and wicked extravagance in the rush for new business is over. Under the new laws the commissions to agents, hitherto anywhere from 60 to 90 per cent. of the first year's premium, will be reduced. In the cost of new business necessarily are included the fees paid to medical examiners. Their fees have been modest and wholly inelastic; the majority of New York companies have paid their examiners a uniform fee of $5, or £1, an examination, irrespectively of any amount under $25,000, or say £5000 sterling. When that sum has been applied for examinations by two examiners were in order, each receiving the $5 fee, plus a fee of $3, or 12*s.*, to one of them for a microscopic examination of the urine. The close and faithful medical examinations of the past, through which a carefully selected line of risks was secured, naturally have resulted in a small mortality. The latter saving has enabled the companies to amass large surplus accumulations, amounting to many tens of millions of dollars. In the reduction of the fees hitherto paid to examiners by the New York companies a hardship will accrue to the medical examiners. They have not been overpaid. Upon a faithful and conscientious discharge of their duties rests the stability of the companies. The work performed by them exacts tact, experience, and special training, to say nothing of endless patience. The fees are to be reduced, such is the current belief—a reduction in fees here in this State, as well as in all parts of the United States, for the companies now under discussion. The changes now impending have produced some apprehension among the life insurance examiners of New York and of other States as well. In some distant States, notably in the South and South-West in part, county medical societies have attempted to stem the rising tide by placing new rules and regulations on their minute books, and under their respective rulings their members are informed what they shall accept as remuneration for medical examinations for life insurance companies. In other words, no member can accept less than the fee fixed by the medical society to which he belongs.

May 5th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Bubonic Plague.

BUBONIC plague has broken out once more in Sydney, Brisbane, and West Australia. The disease was first noticed in rats and after an interval affected human beings. The health authorities in New South Wales are of opinion that the outbreak is due to a fresh infection brought by rats from over-sea. The first outbreak in Sydney occurred in 1901 when there were 301 cases and an average mortality of 30 per cent. In 1902 150 cases were reported; in 1903 only two cases; in 1904 12 cases; and in 1905 18 cases. The average mortality of all these was about 25 per cent. The last case of plague in Sydney previously was on July 12th, 1905. In December, 1905, and at intervals since up to the present, plague-infected rats have been caught, chiefly near the wharves; recently they have been found in the city. On March 11th a rat caught in a building in Kent-street was found to be infected and on March 12th a woman working there was attacked with plague. She said that a dead rat had been removed from under the seat in the workroom which she occupied. Since then three more cases have [illegible] building. Eight cases have been reported [illegible] occurred at G[illegible] proved fatal.

pneumonic form of plague were found in Perth and 25 per cent. of all rats caught were plague infected. The health authorities in all the States are urging more thorough destruction of rats. In Victoria the Board of Health has decided to enforce the regulations for shipping from other ports unless it was known that no infected rats could be found in the other States. The restrictions differ in each State and it is highly desirable that they should be uniform.

Typhoid Fever.

Typhoid fever is very prevalent at Kalgoorlie, West Australia, the local hospital being full of cases. At South Melbourne, Victoria, a case occurred in a dairy. About 40 cases have been reported in the municipality since the beginning of the year and the majority within the last fortnight. The local health officer had his suspicions aroused and made an investigation of the dairies and milk-supply. In 16 cases the milk-supply was from one dairy and there it was found that a child was ill and on investigation the illness proved to be typhoid fever. The authorities promptly stopped the sale of milk and ordered the premises to be made satisfactory. Further inquiry showed that the original source was an outbreak of typhoid fever at the country farm where the milk came from.—The principal medical officer of the Army Medical Corps of New South Wales has reported that the rifle range at Randwich was not in a fit sanitary condition for holding the usual Easter camp as a case of typhoid fever had occurred at a cottage at the entrance to the range three months ago.

Vital Statistics of Melbourne.

The population of Melbourne on Dec. 31st, 1905, was 515,350. The excess of births over deaths was 5351. The deaths from tuberculous diseases for 1805 were less than for any year since 1901, when they numbered 989 and 827 in 1905. The death-rate from typhoid fever was also low—viz., 41.

Waste of Infant Life.

At a deputation to the Queensland Government on the subject of infant life protection Dr. A. Jefferis Turner stated that "in his opinion it would be no exaggeration to say that over 80 per cent. of bottle fed babies died during the summer months in Brisbane," and Dr. Eleanor Bourne of the Brisbane Children's Hospital said that the majority of babies brought there "suffered from the effects of improper feeding and nothing else." Mr. P. E Muskett of Sydney some time ago pointed out that in 19 years up to 1902 inclusive there were 345,096 deaths of children under five years of age in Australia and New Zealand; of these, 303,070 were infants and probably 150,000 of these deaths could have been prevented.

The Delivery of Milk and Health.

A dispute between the Milk Carter's and Dairymen's Union and the New South Wales Fresh Food Company was referred to the Arbitration Court and an important decision has been given. The issues covered various conditions of work but one of the most important was a claim for only one delivery of milk on Sundays, Wednesdays, and holidays. On this question the State Children's Relief Department intervened by permission of the court and evidence was given by experts that two deliveries were necessary in the interests of public health. Dr. W. G. Armstrong, the officer of health of the metropolitan district of Sydney, stated that in 1886 the infant mortality of Sydney was 173 per 1000. Last year it was 89 per 1000. The improvement was, he thought, due to the introduction of the Dairy Supervision Act and its more stringent enforcement. Every advance in securing a purer milk-supply had been followed by a fall in infant mortality. It was most important that milk should reach the consumer as quickly as possible. At the Medical Congress in September a proposition was carried unanimously that a bi-daily delivery of milk in Australasian cities should not be interfered with in any way. Dr. R. J. Millard, assistant Government medical officer, corroborated Dr. Armstrong's evidence. He had made observations showing that milk in Sydney became acid in seven hours, soured in 12 hours, and quite curdled in 24 hours. Professor T. P. Anderson Stuart also gave evidence as to the necessity for two deliveries, as did Mr. Hamlet, Government analyst. The court decided that it was impossible to make an order binding people down not to deliver milk more than once a day. The public health was of paramount importance and time for the men must be found in some other way.

Hospital Affairs.

The board of directors of the Royal Prince Alfred Hospital held a special meeting on March 2nd to consider the question of the appointment of women as resident medical officers. Regulations prescribing the duties of such officers, if appointed, were drawn up, by which they were to be exempted from attendance on adult male patients in certain cases. Subsequently the conjoint board, consisting of the directors and the University Senate, met and decided that as Miss Aspinall went into residence with the approval of the hospital authorities she should be appointed for the year, subject to the above regulation as to her duties, but her appointment is not to be taken as a precedent. It was also decided that the whole question of the appointment of women doctors to the hospital should be considered during the present year by the conjoint board. The directors of the hospital have also been considering the whole system for appointing medical officers by the conjoint board and decided to recommend the appointment of a permanent electoral committee representative of both the senate and the directors which would submit recommendations for the approval of the conjoint board.—At the Sydney Hospital Dr. W. O. Maher, Dr. E. J. Jenkins, Dr. D. S. Bowker, and Dr. T. S. Kirkland were re-appointed to their respective positions on the honorary medical staff for a period of four years.—The committee of the Women's Hospital, Melbourne, has decided to establish a pathological laboratory and to appoint a pathologist to make chemical examinations and to attend on operation days or when required by the staff.—At the annual meeting of the King Edward Seamen's Hospital, Sydney, the annual report showed that 73 indoor and 375 outdoor cases had been treated.—The report of the Carrington Centennial Hospital Home for Convalescents read at the annual meeting stated that 1376 patients had been treated, of whom 1241 were restored to health and 40 were much improved. The committee thought that all the large and well-managed hospitals should be under one committee and that some sort of hospital tax should be imposed for their maintenance.

Balmain Friendly Societies' Dispensary.

Another difficulty has arisen between the Balmain Friendly Societies' Dispensary and its medical officers and the latter have resigned in a body. Their resignation has been accepted and three new men have been appointed.

Obituary.

A very old medical identity has been removed from Victoria by the hand of death in the person of Dr. John Blakemore Phipps who had practised for over 40 years at Lancefield but retired some years ago. He was the son of a medical man and graduated at Edinburgh. He served in the Crimean war and at its close went to Victoria and settled at Lancefield. He was a member of the first local council, was a Justice of the Peace, and coroner for the district. He was 79 years of age. One of his daughters married Mr. J. T. Chapman of Yarra Glen.

Syme Research Prize.

The David Syme research prize of £100 and a medal at the Melbourne University has been awarded to Dr. E. H. Embley for a thesis on the Action of Anæsthetic Quantities of Chloroform upon the Blood-vessels of the Bowel and Kidney and a report on the Pharmacology of Ethyl Chloride.

March 29th.

Obituary.

GEORGE APPLETON, M.R.C.S. ENG., L.S.A.

Mr. George Appleton died at his residence, Park Braws, the Lizard, Cornwall, on May 11th, in his eighty-fifth year. The deceased, who received his medical education at Guy's and St. Thomas's Hospitals, took the qualifications of M.R.C.S. Eng. and L.S.A. in 1843 and 1844 respectively. Shortly after qualifying he was appointed surgeon on one of H.M. troopships, in which he went to India. Returning later in ill-health he took up his residence at St. Keverne, Cornwall. He continued there for some time and many years ago commenced practice at the Lizard and continued in active work there until four years ago. Mr. Appleton had many friends and was highly esteemed. He interested himself in all good works for the benefit of the residents of the Lizard and it was mainly through his efforts that the Lizard reading-room was built. He was for many years vice-chairman of the Helston board of guardians. He was a staunch Churchman. Mr. Appleton leaves three sons with whom much sympathy is felt.

Medical News.

UNIVERSITY OF CAMBRIDGE.—At the third examination for medical and surgical degrees, Easter term, the following candidates were successful:—

Part II., Surgery, Midwifery, and Medicine.—J. D. Barris, B.A., Caius; H. J. Clarke, B.A., Trinity; R. P. Cockin, B.A., Caius; R. M. Courtauld, M.A., Pembroke; W. I. Cumberlidge, B.A., Christ's; R. Davies-Colley, B.A., Emmanuel; J. R. Draper, B.A., St. John's; C. F. Fothergill, B.A., Emmanuel; A. Goulston, M.A., and W. B. Grandage, B.A., Clare; M. Grundy, B.A., St. John's; C. R. F. Hall, B.A., Trinity; G. H. Harper-Smith, B.A., Caius; C. King, B.A., Trinity; S. G. MacDonald, B.A., St. John's; J. McIntyre, B.A., King's; J. T. Macnab, B.A., Christ's; E. H. Mayhew, B.A., and A. W. Moore, B.A., Emmanuel; W. L. Murphy, M.A., St. John's; A. S. M. Palmer, B.A., Jesus; W. H. Robinson, B.A., Downing; C. Stanley-Clarke, B.A., and F. J. Thornton, B.A., Caius; J. H. Trench, B.A., Trinity; A. Walker, B.A., Emmanuel; G. L. Webb, B.A., Caius; C. J. Wilson, B.A., Christ's; H. W. Wiltshire, M.A., Clare, and F. Worthington, B.A., St. John's.

—At the Congregation on May 10th the following degrees were conferred:—

M.D.—G. H. Orton, Trinity; and E. A. Ross, Trinity.
M.B. and B.C.—L. G. Davies, Trinity; and E. H. Mayhew, Emmanuel.
M.B.—N. C. Fletcher, Queens'.
B.C.—C. King, Trinity; J. R. Draper, St. John's; and F. Worthington, St. John's.

—Professor G. Sims Woodhead has been appointed a governor of Cheshunt College.—Professor Newton, F.R.S., has been appointed a manager of the Balfour (Animal Morphology) Fund.—Mr. W. M. Mollison, M.A., Clare, has been approved for the M.C. degree.—The scheme for the Quick Professorship of Biology has been approved by the Senate, and Professor Sims Woodhead, Mr. A. Sedgwick, Mr. A. E. Shipley, Dr. Langley, Mr. J. J. Lister, and Mr. F. F. Blackman have been appointed the first managers of the fund and electors to the chair.—The grace for the exemption of students in science (including mathematics) from the obligation to study both classical languages will be voted upon on May 25th and 26th.—It is proposed to appoint Dr. G. H. F. Nuttall, F.R.S., to a newly established Readership in Hygiene in connexion with the Special Board for Medicine.—Mr. W. J. Sell, F.R.S., University lecturer in chemistry, has been approved for the degree of Doctor of Science.—Mr. F. T. Brooks, Emmanuel, has been appointed junior demonstrator of botany.—The University library has received a gift of £5000 from the Worshipful Company of Goldsmiths. —The department of agriculture has received promises of contributions amounting to £9000 towards the cost of erecting new buildings.

ROYAL COLLEGES OF PHYSICIANS AND SURGEONS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW.—At the May sittings for diplomas in Public Health held in Glasgow the following candidates passed the respective examinations:—

First Examination.—John Hunter, Musselburgh, Alexander Edington, Edinburgh; Frederick E. Stokes, Crosshill, Glasgow; George Broadfoot Serle, Singapore, Straits Settlements; and Edward Percy Calder, Coldingham, Berwickshire.
Second Examination.—David Robertson Dobie, Crieff; Murdoch Macdonald, Shettleston, Glasgow; Alexander Edington, Edinburgh; George Broadfoot Serle, Singapore, Straits Settlements; Frederick Ernest Stokes, Crosshill, Glasgow; William Hamilton Simpson, Scalby, R.S.O., Yorkshire; and John Alexander Kennedy, Bearsden, Glasgow.

FOREIGN UNIVERSITY INTELLIGENCE.—*Amsterdam:* Dr. H. J. Brongersma has been recognised as *privat-docent* of Urology.—*Bologna:* Dr. Silvio Tonnini of Messina has been appointed to the chair of Mental Diseases in succession to Dr. Roncati, resigned.—*Budapest:* Dr. Josef Arkövy has been appointed Extraordinary Professor of Odontology. Dr. Arnold-Winternitz has been recognised as *privat-docent* in Surgery.—*Copenhagen:* Dr. Fr. Pontoppidan has been recognised as *privat-docent* of Otology.—*Cracow:* Dr. Emil Godlewski has been promoted to an Extraordinary Professorship of Anatomy and Embryology.—*Halle:* Dr. A. Stieda has been recognised as *privat-docent* of Surgery. —*Marburg:* Dr. Hermann Küttner, Extraordinary Professor of Surgery, has been promoted to an Ordinary Professorship.—*Montreal (McGill University):* Dr. J. W. Stirling has been promoted to the Chair of Ophthalmology in succession to the late Professor Frank Buller.—*Munich:* The rank of Professor has been granted to Dr. F. Bezold, Extraordinary Professor of Otology.—*Naples:* Dr. Filippo Bottazzi has been appointed Extraordinary Professor of Experimental Physiology.—*Philadelphia:* Dr. Edw. Anthony Spitzka has been elected Professor of General Anatomy at Jefferson Medical College.—*Pisa:* Dr. Arbace Pieri has been recognised as *privat-docent* of Psychiatry.—*Rome:* Dr. Amico Bignami has been promoted to the Ordinary Professorship of General Pathology.—*Vienna:* Dr. Alois Kreidl has been granted the rank of Ordinary Professor of Physiology.

PROPOSED PUBLICATIONS ON SMALL-POX BY THE METROPOLITAN ASYLUMS BOARD.—The Metropolitan Asylums Board decided some months ago to publish two works on the subject of small-pox—viz., "The Diagnosis of Small-pox" and "Small-pox and its Relation to Public Health," and made the usual application to the Local Government Board for sanction to the necessary expenditure. At a meeting of the board on May 12th a letter was read from the Local Government Board in reference to the proposal, stating that it had no authority to express an opinion as to the legality of any expenditure in connexion with the publications mentioned, but that it was a question which the auditor must determine in the first instance and that it considered that the best course for the managers to take would be to arrange for the publication of "The Diagnosis of Small-pox" by a publisher at his own risk. It also suggested that the question of publishing a book on "Small-pox and its Relation to Public Health" should stand over until after the book on "The Diagnosis of Small-pox" had been issued. The communication was referred to the hospitals committee for consideration and report.

THE JUBILEE DINNER OF THE INCORPORATED SOCIETY OF MEDICAL OFFICERS OF HEALTH.—The members of the Incorporated Society of Medical Officers of Health dined at the Hotel Cecil on Friday last, May 11th, Sir Shirley F. Murphy, President of the society, presiding. The occasion was the jubilee of the society. An interesting account of the foundation and work of the society had been previously given in an address by Sir Shirley Murphy, which will be found in another column of THE LANCET. Among the visitors present were Sir R. Douglas Powell, President of the Royal College of Physicians of London, Mr. John Tweedy, President of the Royal College of Surgeons of England, Baron Kanehiro Takaki, Mr. Evan Spicer, chairman of the London County Council, Surgeon-General Keogh, Director-General of the Army Medical Service, Sir William H. Broadbent, Sir James Crichton-Browne, Sir Michael Foster, Sir T. Lauder Brunton, Sir John McFadyean, Sir Patrick Manson, Sir Melvill Beachcroft, Sir H. Seymour King, M.P., Dr. F. W. Pavy, Dr. J. F. W. Tatham, and M. Henri Monod. In proposing the toast of "The Houses of Parliament" Mr. Tweedy said that no section of the country had a more intelligent appreciation of the importance of public health than those who represented the working men in the House of Commons. They represented not only labour but the sturdy thought of the working people and they thoroughly recognised the work which had been done by public health officers. Sir Seymour King, in responding. suggested that the President of the Local Government Board should be elected by the Society of Medical Officers of Health, and the proposal has more sound sense in it than perhaps the speaker realised. The toast of "Local Government" was proposed by Sir Michael Foster, who said that the training of medical officers of health was necessarily most complicated. It was long, wide, and varied, and the emoluments should be such as would justify the long training which was necessary. A medical officer of health should have adequate powers given him to carry out the measures which his training suggested as being applicable to particular circumstances. Mr. Evan Spicer, chairman of the London County Council, who responded, spoke of the gratification of the County Council in seeing the presidential chair of the society occupied by Sir Shirley Murphy, whose work in the interests of public health would always be appreciated by the members of the council. Sir James Crichton-Browne, in proposing the toast of "The Society of Medical Officers of Health and their Jubilee," spoke of medical officers of health as thorough-going protectionists who were safeguarding the public weal by prohibiting the importation of disease. During the past half century the society had been identified with every advance in the science of preventive medicine and he trusted that before long it would obtain a Royal Charter and the patronage of the King. In associating with the toast the name of the President of the society he referred to the public health work during the past 30 years of Sir Shirley Murphy whom he described as first a pioneer, then a leader, and now a generalissimo. Sir Shirley Murphy, in response, said that without the society the medical officer of health would be a less efficient person than he is. Their work was making progress in efficiency and in influence and it behoved them to see that they did not disappoint expectation. It was especially gratifying to find that from all quarters of the world their assistance was sought. Dr. Pavy also responded and said that although 50 years ago they knew nothing of bacteria yet they had vague notions of disease germs; he also referred to the early days of the society, the first meeting in connexion with which was held in his house. "The Visitors" was proposed by Dr. Arthur Newsholme and Baron Takaki, in responding, spoke of the admiration entertained by the Japanese for the British methods of public health administration, though in one respect they were not slavish followers of this country, for they were great believers in the efficacy of vaccination. There were no anti-vaccinationists in Japan. Every child was vaccinated before it was six months old, revaccinated when it entered school at six years, again revaccinated at 14 years when going to the middle school, and the men were revaccinated before entering the army, while a further revaccination was enforced if an outbreak of small-pox occurred. Sir R. Douglas Powell also very briefly replied. A band played during dinner and afterwards songs and recitations were given. The company did not separate till a late hour, all present agreeing that the jubilee dinner of the society had been a great success.

ABUSE OF MEDICAL CHARITIES IN NOTTINGHAM.—A large and representative meeting of the profession in Nottingham and the neighbouring district, convened by the Nottingham Medico-Chirurgical Society and the Nottingham division of the Midland branch of the British Medical Association, was held on May 9th, under the presidency of Mr. T. J. Dabell, when the following motion, proposed by Dr. W. Tibbles and seconded by Dr. W. B. Ransom, was brought forward, discussed, and carried unanimously:

> That abuse exists and that this meeting invites the governors of the respective charities in Nottingham to consider what steps can be taken to prevent it.

Dr. Tibbles, in proposing the motion, attributed the increasing abuse of hospitals to (1) indiscriminate distribution of letters of recommendation; (2) the increasing desire for pleasure and luxury amongst the masses, necessitating economies in other directions, such as medical attendance: and (3) the expansion of the hospitals themselves, the increase of their staffs, and the creation of new and additional institutions. The number of patients treated at the various charities in Nottingham had increased from 24,668 in 1885 to 45,147 in 1904, the latter figure being about 20 per cent. of the entire population of Nottingham. Thus at the same rate of increase the numbers would be actually doubled in 22 years, while the increase of population did not exceed 25 per cent. Until some system of inquiry was established neither the governors nor anyone else would have any means of determining the social status and financial position of the vast majority of those who were treated by them. Many striking examples were then given of abuse of the charities and at one institution the poorer patients said that they felt ashamed to sit alongside the very respectable persons who waited their turn for treatment. Others drove up in cabs, which were kept waiting while the patient attended his medical adviser and then returned to his home or employment. In some cases tradespeople gave away to their customers recommendations to the various charities as an inducement to the sale of their goods. Dr. Ransom, in seconding the motion, traced the various steps of a similar movement on the part of the profession in Nottingham eight years ago, which unfortunately achieved nothing. The agitation had then dropped with the understanding that an inquiry officer would be appointed as soon as the out-patient department had been rebuilt and remodelled. This understanding had never been carried out, although the alterations then contemplated had since been completed.—The President pointed out that if the meeting had the result of directing the funds subscribed by the charitable into what were more eligible channels, it would not only safeguard the medical profession but do a service to the cause of charity generally.—Dr. J. A. Waring laid stress on the fact that many persons were ignorant of the fact that hospitals were intended for free treatment and went there fully meaning to pay something.—Dr. W. Hunter, Dr. J. S. Bolton, Mr. G. B. Wray, and Dr. T. W. Kelly also joined in the discussion.—The following motion, which was proposed by the President and seconded by Dr. Lewis W. Marshall, was also carried unanimously:—

> That this meeting begs to suggest that some system of inquiry be made into the financial status of every person presenting himself or herself for treatment, in order to ascertain if they are suitable recipients of medical charity. The meeting desires also to express the opinion that the present system of recommendations is of doubtful value and should be modified.

This motion was spoken to by Mr. R. C. Chicken, Dr. Ransom, Dr. J. F. Blurton, Dr. Hunter, and Dr. Waring.

MEDICAL MAGISTRATE.—Mr. David Denzil Harris, M.B., C.M. Glasg., has been placed on the commission of the peace for the borough of Carmarthen, Wales.

PRESENTATION TO A MEDICAL PRACTITIONER.—Mr. A. G. B. Lory, L.S.A., on relinquishing his practice at Chudleigh, Devon, was recently presented by the members of the Loyal Chudleigh Lodge of Oddfellows with a Dent's clock as a token of their esteem and respect for his services as their medical officer for a period of more than 11 years. The clock was suitably inscribed.

QUEEN VICTORIA'S JUBILEE INSTITUTE FOR NURSES.—Satisfactory progress, the report of this institute states, has been made during the year 1905. The affiliated associations and the nurses at work continue to increase steadily year by year. Two new county nursing associations, in Herefordshire and Berkshire, have been affiliated and the work in each of the existing affiliated county associations has been extended. The demands on these associations as well as on the institute for trained midwives for country districts have been more numerous owing to the Midwives Act of 1902, which is now come into operation. Throughout the year the council has been endeavouring to provide for the serious deficit in the income of the institute which will take place in 1906. This is due to the exhaustion, save for a small sum, of the capital provided by the Queen's Commemoration Fund of 1897 which was to be expended in promoting the extension of the work. With the disappearance of this fund the council is faced with a deficit of some £2000 a year. Every effort has been made to reduce expenditure, but with the ever-increasing roll of affiliated associations and the consequently growing liabilities in the direction of inspection and training of nurses it is impossible to curtail expenses to any great extent without serious detriment to the efficiency of the work.

SOUTH LONDON DISTRICT NURSING ASSOCIATION.—Princess Louise Duchess of Argyll, the President of the South London District Nursing Association, supported the Lord Mayor at a meeting at the London Mansion House on May 9th in aid of the above association. The committee, in its twenty-second annual report, stated that the number of patients last year was 2176, while the visits paid to the sick poor in their homes numbered 44,222. Of the 2111 cases sent in during the year 1153 were by medical men and 43 by hospitals, 391 by ministers of religion, 486 by patients' friends, and 34 by the Charity Organisation Society. Canon Erskine Clarke (the chairman of the committee) proposed a motion calling upon the charitable public to support the work of the association. The motion was seconded by Mr. T. F. Schwann (the honorary treasurer) and adopted. Sir Joseph Dimsdale proposed a motion approving the principle of nursing the sick poor in their own homes. This was seconded by Sir William H. Bennett, K.C.V.O., and supported by Archdeacon Wilberforce and carried unanimously. A hearty vote of thanks to her Royal Highness for her great practical sympathy with the aims and objects of the association and also to the Lord Mayor terminated the meeting. Tea was subsequently provided by the Lord Mayor in the long parlour.

Parliamentary Intelligence.

HOUSE OF LORDS.

FRIDAY, MAY 11TH.

Poisons and Pharmacy Bill.

In the House of Lords on Friday, May 11th, the report of amendments made by the Standing Committee on the Poisons and Pharmacy Bill was received. Further amendments were now moved.

Clause 4 provided that "No body corporate shall carry on the business of a pharmaceutical chemist or chemist and druggist unless in every premises where the business is carried on the business is *bonâ fide* conducted by a manager or assistant being a duly registered pharmaceutical chemist or chemist and druggist, as the case may be, nor unless the name of the person so qualified is conspicuously exhibited in the shop or other place in which he so conducts the business; subject as aforesaid anything which would be an offence under Section 15 or Section 17 of the Pharmacy Act, 1868, if committed by an individual, shall be an offence under those sections if committed by a body corporate: Provided that notwithstanding anything in this section a body corporate may continue to use any description which it was accustomed to use before the 1st day of April, 1906."

Lord EBURY moved to leave out all the words after "business" and to insert instead: "and any body corporate carrying on such business and failing to comply with the provision of this section shall be guilty of an offence under Sections 15 and 17 of the Pharmacy Act, 1868, and liable to the penalties therein mentioned" He said that large businesses for retailing drugs had developed very much within the last 30 years, as retail chemists had charged such high prices. The companies had been able to undersell the ordinary retail chemists and to obtain a satisfactory return on capital. The retail chemists and the Pharmaceutical Society had been endeavouring for some years by Bills and by "*peaceful persuasion*" in the lobby to induce the legislature to put a spoke in their rivals' wheel. Finally, they had had the good fortune so far to enlist the sympathy of the Earl of Crewe as to induce him to insert this clause in this Bill which contained little else of a contentious nature. He thought the adoption of the first seven lines of the clause was expedient in order to settle by statute the position of companies which had hitherto rested on a common law basis. But the latter part of the clause, by invoking certain sections of the Pharmacy Act of 1868 and by reversing the legal decision in their lordships' House, pronounced in 1880, deprived all corporate bodies of the right of describing themselves as chemists. He claimed the right to the designation for all companies selling drugs through qualified assistants If the business was conducted in accordance with the first part of this clause a complete guarantee was afforded for the public safety. It was of no consequence whether the owner was an individual, a partnership, or a joint-stock company. The designation of chemist and druggist was necessary to attract the attention and to gain the confidence of customers The title should not be given to one class more than another, in view of the fact that they all employed adequate skill and knowledge in the conduct of the business. What was proposed was not only protection but protection in an injurious form. The chemist who served a company had passed a qualifying examination just the same as the chemist who traded individually.

The Earl of LICHFIELD, who seconded the amendment, said that in committee the noble Earl in charge of the Bill had altered the clause in such a way that in future it would be impossible for corporate bodies to call themselves by the name of chemists. From time immemorial they had been able to call themselves by this designation. In 1880 the House of Lords decided that it was competent for them to do so. The Pharmaceutical Society claimed that the word chemist should be a personal one and should only apply to those who had passed the necessary examination. But under the Act of 1868 every company was obliged to keep a qualified manager in every shop it owned and therefore the safety of the public was as well preserved in the case of companies as in the case of individuals. Great sums of money had been invested in the business on the strength of the existing law and he wanted to know what harm the companies had done in the exercise of their rights. The clause would vexatiously affect trade and it was not in the public interest that a privileged class should be established and companies debarred from using the name chemist.

The Earl of CREWE said he gathered from the speech of the noble lord and the amendment that this was a matter that had been in dispute for many years between the Pharmaceutical Society and the companies and it might really be described as a storm in a teacup, though those interested in the question considered it a matter of primary importance. The Act dealing with chemists and druggists was that of 1868 and it made it unlawful for any person to use the words "chemist and druggist" unless he was a person qualified by examination. Since that time no alteration of practice had been made in the law, but companies had sprung into existence, many of them very large concerns, and no doubt they had been of distinct service to the public by creating a healthy competition, for they had to a great extent lowered the price of drugs The chemists said the Act of 1868 conferred upon them a distinct assurance of title, they regarded the title as absolutely applying to the individual and contended that it should not be used by a company which had not passed any examination On the other hand, the companies pointed to their excellent public record and the fact that they employed a qualified chemist in each shop and therefore the public had no further interest in the use of the term; in fact, it was a sort of domestic matter between rivals in trade The simple issue was this, was a chemist an ordinary tradesman, like a butcher or baker, or was he in the position of a man who had taken a degree, and therefore alone entitled to the use of the title? That really was the whole point at issue. He admitted there was a great deal to be said on both sides, but on the whole he had arrived at the definite conclusion that these titles, under the Act of 1868, were personal, that to some extent they were in the nature of a degree or qualification and ought not therefore to be attached to any name except that of the man who had actually earned them. If that were so it destroyed the two principal arguments of noble lords opposite, because if a title was a personal matter no one else was entitled to the use of it. People took a distinct pride in the possession of these titles of pharmaceutical chemists and naturally did not like to see persons who had not been through the mill as they had using these distinctions when they had not earned them. They were told that an enormous injury would be inflicted upon these large companies if they were not allowed the use of the title of chemist, a title by which the public were attracted rather than by the title of "druggist" or "dealer in medicine." For his part he did not consider that that was a point of difficulty, as he believed that the public were guided more by the particular kind of shop and were drawn to the shop at which they had been in the habit of dealing With regard to companies he believed that the public were attracted more by the appearance of the place, by the obvious business like manner in which the shop was carried on, as was the case in many of these companies, rather than by the name over it, and therefore would prefer to go to one of these brilliant stores where they might be sure of getting the proper thing than going to some frowsy looking shop with the word "chemist" over the door. He therefore thought that the injury these companies said they would receive by the loss of these titles was enormously exaggerated. On the other hand, no doubt they would suffer in a different way. No doubt in many cases, and one case in particular, they had adopted the title of "chemist" on the shop-front and if this Bill passed as it stood those shop-fronts would have to be abandoned and a very considerable number of labels would have to be sacrificed This fact, of course, gave them a claim to a considerable time limit in which to minimise the injury Consequently he should be prepared to propose a time limit of seven years which he thought would be sufficient to meet the case

Viscount ST. ALDWYN said that undoubtedly the injury inflicted upon these companies would be very great if the Bill were passed as it stood. He had been informed that there was one company in existence which had as many as 320 shops throughout the country at which 4000 qualified assistants were employed and the capital embarked amounted to £1,300,000. The expenditure of this company upon shop-fronts and other things on which the word "chemist" appeared had been considerable and by the passing of this Bill this company would lose between £30,000 and £40,000. That, he submitted, was a fine of a very large amount to impose upon a body that was doing no more than an admirable work for the benefit of the public at large. He was quite sure their lordships would not desire to do anything that would be unfair to existing companies and fine them so heavily as he had described. The amendment before them, however, raised a larger and wider issue, it raised the whole question of not only whether existing companies should be allowed to maintain their position, but whether future companies should be allowed to enter into competition with them The noble earl had referred to past history. The Act of 1852, which he believed was a Government statute, in this matter certainly forbade, in accordance with previous legislation, the use of the title "chemist and druggist" to anyone not qualified by passing an examination. But the Act also forbade any person not so qualified from even opening a shop. Now, however, the noble earl did not intend to prevent these companies from keeping open shop in the future; that was not a provision that would commend itself to this House or the Government, but what the noble earl allowed was the keeping open shop, forbidding them to use the title "chemist and druggist" after a certain number of years. What the noble earl proposed was that a person carrying on the business should not be allowed to call himself by the proper title applicable to the business An individual might have 30 shops with an assistant and he could continue the business.

The Earl of CREWE: Provided the assistant was a qualified man.

Viscount ST. ALDWYN said he was advised that the noble earl's proposal would only apply to companies and not to individuals. But what was the history of this matter? He knew a good deal about it, because when he was a member of the other House he was approached by certain of his constituents to forbid the competition of companies in the sale of drugs. He replied that that was a monstrous proposal and he was then asked if he would compel every director of a company to be a qualified pharmaceutical chemist. He admitted that was less objectionable. The fact was that the Pharmaceutical Society had been desirous throughout to secure a trade monopoly for their own benefit and to the public injury by the keeping up of prices Was it possible that a free trader like the noble Earl would attempt to establish a monopoly in order to further the protectionist desires of the Pharmaceutical Society?

Lord STANLEY of ALDERLEY said it seemed to him that the name "chemist" was like that of an old-established firm, a trade name, and therefore he could not see why they should seek to take it away from a company which employed qualified men to carry on the business.

The Marquis of RIPON said it appeared to him to be a misuse of terms to allow companies composed of large bodies of shareholders to use the words "chemist and druggist." The loss that would be occasioned would no doubt be very large, but he thought it was greatly exaggerated, as those who were concerned in matters of this kind always estimated their losses very highly. His noble friend recognised that there would be a loss and he gave them seven years in which to recoup themselves so far as possible. In his opinion it was far better that a name in which the public had confidence should be confined to those persons who had undergone a proper examination.

Lord BELPER said he would ask whether it was the case that the title of pharmaceutical chemist was really kept up as a personal one. In this Bill it was laid down that the executor of the estate of a deceased chemist could continue the business as long as it was conducted by a registered pharmaceutical chemist or chemist and druggist. The executor did not require to be a chemist itself. Yet the clause would prevent a company employing such a chemist from describing itself as chemist. As far as he could understand the companies had carried on their business exceptionally well, so much so that the public had come to look on them as a necessity. A very large number of petitions had been signed by the customers of those companies who were perfectly satisfied and wished the business to be carried on in the same way as hitherto Why should not an association of individuals be allowed to carry on a business in the same way as a pharmaceutical chemist who did not himself attend to his business so long as the public were assured that the business was properly conducted?

The Earl of CREWE said that he did not mean to provide by the Bill that executors should be allowed to carry on under a particular name with the word chemist attached unless that chemist still existed. He would be glad to add words to the Bill to prevent that.

Their lordships divided.

For the amendment	38
Against	32
Majority for	6

The amendment was accordingly carried.

Lord LAWRENCE moved to leave out Clause 7 which provided that the Bill should not apply to Ireland and to insert the following clause:—

7. This Act, except Sections 3 and 4 thereof, shall apply to Ireland subject to the following modifications —

(a) For references to the Pharmacy Acts, 1852 and 1868, or either of them, there shall be substituted references to the Pharmacy Act (Ireland), 1875, and the Poisons (Ireland) Act, 1870, Pharmacy Act (Ireland), 1875, Amendment Act, 1890 and for references to particular provisions of the first-mentioned Acts shall be substituted references to the corresponding provisions of the last mentioned Acts, and in particular for the reference to Schedule A to the Pharmacy Act, 1868, shall be substituted a reference to Schedule A to the Poisons (Ireland) Act 1870 and for the reference to Section 2 of the Pharmacy Act, 1852, shall be substituted a reference to Section 16 of the Pharmacy Act (Ireland), 1875

(b) For the reference to the Council of the Pharmaceutical Society there shall be substituted a reference to the Council of the Pharmaceutical Society of Ireland

(c) For references to Orders in Council by His Majesty there shall be substituted references to Orders in Council by the Lord Lieutenant

(d) Section 17 of the Pharmacy Act (Ireland), 1875, Amendment Act, 1890, shall apply where the persons keeping open shop are a company

said that Irish agriculturists had not the same facilities as those in gland for purchasing poisons required in their industry Irish icultural societies were unanimously in favour of the clause he posed and the only opponent was the Pharmaceutical Society of land That society had a monopoly and it was not in the public erest that that monopoly should be continued

he Earl of DONOUGHMORE said that when the Bill was before the ouse on a previous occasion an amendment of his excluding Ireland s carried. The Bill was founded on a report of a Departmental mmittee appointed by the late Government. Ireland was in no way erred to that Committee and no evidence was taken as to the condi n of affairs in Ireland. He believed that this was a case in ich Ireland was very much better governed than England. der the Act of 1868 no one could sell poisons of any nd unless he was a registered chemist. This was incon nient in regard to poisons for agricultural purposes This evil s recognised in Ireland 15 years ago and the Act of 1890 was passed which the Pharmaceutical Society was given power to license uggists to sell poisons for agricultural purposes only but without erty to make up poisons for medicinal purposes. There were 1567 rsons in Ireland licensed in this way and they were to be found in arly every town and village of any importance. He had seen a list 130 places which were supposed to need further accommodation but had been carelessly drawn up and was inaccurate. He knew several aces which were on the list and which in reality had persons licensed sell poisons The Irish Cattle Traders Association had circulated pers among their lordships in which it said that the dangers of eep scab would be augmented if the Bill passed as now drafted. It as, however, quite obvious that the Bill would not cause the slightest iminution in the number of persons qualified to sell poisons in eland The law would remain as it now was The 1500 censed people all appeared to be genuine chemists and they erfectly met the convenience of the public. It would be ery unwise to have a system under which some druggists would be censed by the Pharmaceutical Society and some by the county ouncils. A conflict of authority would arise and it would be difficult prevent the power to sell falling into the hands of unqualified ersons.

The Earl of MAYO supported the amendment. Ireland, he said, was purely agricultural country and if it wanted one thing more than nother it was facilities for getting poisonous sheep-dips and other oisonous compounds Surely the views of societies like the Irish attle Traders and Stockowners Association should be entitled to some eight. The departmental committee, to which reference had been nade, had stated that in modern times these sheep-dips, usually con aining strong poisons, had come into universal use and were indis ensable to sheep farmers. Unluckily sheep scab was very common in reland and in some districts it was almost impossible to get these dips It was all very well to say that there were 1500 people who sold them, out what was that in a population of 4 000 000? It was absolutely necessary that the Bill should apply to Ireland.

The Earl of CREWE said that he had discussed the subject with many gentlemen since the last occasion when the Bill was before the House and he had gathered that the Irish were of opinion that Ireland should be included in the Bill. He confessed that he had not contemplated that this matter would come up again but he had not the least doubt that the clause would have been re-introduced in the House of Commons In the circumstances he did not feel called upon to oppose the amendment.

The Marquis of LONDONDERRY thought that the Earl of Crewe had shown a remarkable change of front. He still thought that it would be unwise to include Ireland but he would advise the Earl of Donoughmore not to press his opposition

The amendment was agreed to and this closed the discussion on the Bill.

HOUSE OF COMMONS

WEDNESDAY, MAY 9TH

Infant Mortality A Conference.

Mr ALDEN asked the First Lord of the Treasury whether, in view of the fact that the report of the *Registrar-General* indicated a serious condition of things as regards infant mortality in certain large industrial towns and areas, he *would* consider the advisability of appointing a departmental committee to investigate the causes of such mortality, with power to call for special reports from, or institute inquiry into the towns and areas concerned.—Sir HENRY CAMPBELL-BANNERMAN replied: I am fully alive to the importance of this question, and as my honourable friend will see from an answer which I gave yesterday, the Local Government Board is taking active steps to ascertain the causes of excessive infant mortality with a view to the adoption of remedial measures. I may mention that a conference which will be attended by a large number of representatives of municipalities is shortly to be held to consider the whole question, and I understand that it is to be presided over by my right honourable friend the President of the Local Government Board. I do not think that, in these circumstances, it is necessary to appoint a departmental committee.

The National Physical Laboratory

Mr. WILLIAM PEARCE asked the Secretary to the Treasury whether commercial tests, chemical or physical were being undertaken at the National Physical Laboratory or were included in the circular of charges of the laboratory; and, if so, whether such competition with private practitioners would be stopped, as being contrary to the recommendations of the Treasury Committee in 1895 and to the declared objects of the laboratory.—Mr M'KENNA answered Except for Government work and for some few special cases which come individually before the committee chemical analyses are only undertaken by the National Physical Laboratory when required to elucidate some physical or mechanical question under investigation The average number of chemical tests of all kinds during the past three years has been 39 The number of physical tests made and of instruments tested has averaged nearly 30,000. Physical tests, including tests on instruments, are undertaken in accordance with the recommendation of the Treasury Committee of 1895, establishing the laboratory as a public institution "*for standardising and verifying instruments, for testing materials, and for the determination of physical constants.*" The members of the Treasury Committee with one exception became original members of the Executive Committee, and they have been careful to keep their work within the terms of the report. The committee is *fully* prepared to consider any complaints which may be made as to the nature of the testing work done and its rates of charges

THURSDAY, MAY 10TH.

Aliens and Infectious Disease.

Mr CLAUDE HAY asked the Secretary of State for the Home Department how many aliens suffering from infectious disease were last year treated at the port sanitary hospital at Denton, Gravesend, and what expenditure was incurred in their treatment Mr Hay also asked the Secretary of State for the Home Department whether aliens who had been treated for infectious disease at the port sanitary hospital at Denton, Gravesend, were, when discharged as convalescent, examined by an immigration officer as alien steerage passengers coming within the scope of the Aliens Act or were discharged from the hospital without such examination—Mr. GLADSTONE said Perhaps I may answer these two questions together I am informed by the town clerk of the City that the number of aliens suffering from infectious diseases who were treated at the port sanitary hospital at Denton near Gravesend during the year 1905 was 36 and the proportion of expenditure incurred in the treatment and maintenance of such aliens was £485. This expenditure is borne entirely by the Corporation of London out of its corporate *funds* and not by the rates. No charge is made either to shipowners or patients. Any such alien who was *liable* on his arrival in this country to inspection under the Aliens Act has, by virtue of Rule 9 made thereunder, to be inspected before release from hospital.

An Irish Contract for Medicine

Mr POWER asked the *Chief Secretary to the Lord Lieutenant* of Ireland for what reason the Local Government Board of Ireland refused to sanction the action of the Kilmacthomas board of guardians in giving the contract for the supply of medicine to the union to Messrs Boileau and Boyd of Dublin, a well known firm; whether he was aware that Messrs Boileau and Boyd's tender was only 1¼ per cent. higher than the tender of Messrs Sumner of Liverpool; and that the Local Government Board sanctioned the action of the Dungarvan board of guardians, who gave the contract *for the supply of medicines* to Messrs. Boileau and Boyd, though in the case of Dungarvan the tender of Messrs. Boileau and Boyd was 1¼ per cent. higher than *the tender of* Messrs. Sumner—Mr. BRYCE replied The board of guardians of Kilmacthomas union advanced no reason for its proposal to accept the higher tender and upon its attention being called by the Local Government Board to its regulation on the subject the guardians decided to accept the lower tender The Dungarvan board of guardians advanced good *reasons* for not accepting the lower tender and the Local Government Board accordingly assented to its application that it might accept the higher tender

FRIDAY, MAY 11TH.

Reform of the Royal College of Surgeons of England.

Sir WILLIAM COLLINS asked the First Lord of the Treasury whether he would be *prepared* to consider a petition having *for* its object a reform of the Royal College of Surgeons of England with a view to giving some voice in the management of the College and its property to the Members of the College—Sir HENRY CAMPBELL BANNERMAN replied I shall be glad to consider any petition which my honourable friend may send me. But, as he is no doubt aware, any change in the *constitution* of the Royal College of Surgeons of England can only be carried out by legislation unless such change has the support of the governing body of the College.

MONDAY, MAY 14TH.

Vaccination in the Army

Mr. LUPTON asked the Secretary of State for War whether the average annual strength of the British armies in Egypt and *India during the 20 years* 1881 to 1900 was approximately 69,751, and the total number of cases of small pox amongst those men 1149, and the total number of deaths from small pox 113, and *whether* seeing that during the same period the town of Leicester had an average annual population of 165,415, and that the total number *of cases of small* pox in *Leicester* during that period was 447, and the total number of deaths from small pox was 31, that the soldiers were all vaccinated *and the* population of Leicester largely unvaccinated, and that the death rate from small pox in the army per 100 000 was eight times the death-rate in Leicester, he would consider the advisability of relaxing the regulation for compulsory vaccination in the army.—Mr HALDANE answered: It is not clear what value can be obtained *from* a comparison between the statistics of Leicester and those of the British army in India and Egypt, but if my honourable friend will consider the statistics for the years 1901 *to* 1904 he *will find* that while the troops in India and Egypt had 165 admissions to hospital for small pox and 21 deaths, Leicester had 740 admissions *to hospital* for small pox and 30 deaths. There would not appear to be any sound grounds for relaxing the regulations for vaccination in the army.

Sleeping Sickness

Mr REES asked the Under Secretary *of State for* the Colonies whether *he* was aware that the sleeping sickness was now reported to have reached Lake Mweru, in Northern Rhodesia, and whether, in view of this fact and of the facts that the mail carriers between Chiromo and *Blantyre had been held* up *by lions* and that the construction of the Government ox-cart road from Katungas to Chiromo was abandoned on account of the presence of the tsetse fly, he would consider the advisability of calling, by telegraph, upon the Commissioner to report regarding the effect of the game preserve alongside the last-named township and to consider whether it could not be removed to some more suitable location.—Mr. CHURCHILL replied: I have heard of some of the reports to which my hon. *friend* refers; but I cannot tell *from any information* in the Colonial Office whether they may not have been exaggerated. *That any connexion exists between* the appearances of lions, of the tsetse fly, and the sleeping sickness on the one hand and the maintenance of the game reserve on the other, is not at present established. But the Secretary of State is addressing *the Commissioner upon* the subject; and if it can be shown that the removal or contraction of the reserve *would increase* the health and security of Chiromo and its environs instructions will be given accordingly.

TUESDAY, MAY 15TH.

Royal Commission on Experiments on Animals.

Sir PHILIP MAGNUS asked the Secretary of State for the Home Department whether he was prepared *to make any statement as to* the appointment of a Royal Commission to consider the working of the Act under which experiments *on animals were permitted for the purposes* of medical research.—Mr. GLADSTONE answered: Yes, sir; in view of *the fact that no inquiry into* the subject has been held *for 30 years* it is the intention of the Government to recommend the appointment of a *Royal Commission* to examine the working of the Cruelty to Animals Act in the light of present scientific knowledge.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

QUACKS AND ABORTION.

THE articles upon Quacks and Abortion which have appeared from time to time in our columns have had the effect of bringing about the disappearance of advertisements dealing with abortifacients from the pages of the better known and widely read newspapers. But in not a few journals we still find advertisements of a bad character. Some of these now lie before us in the advertisement columns of a paper called *English and Home Society* of March 24th. For instance—

BOUTALL'S LADIES' PINK REGULATORS
For Ailments Peculiar to Women.
A SAFE, CERTAIN AND SPEEDY REMEDY
FOR ALL OBSTRUCTIONS AND IRREGULARITIES
Price 2/9 and 4/6. Extra strong, [illegible] and [illegible] per Box.

And another—

BOUTALL'S
STEEL, PENNYROYAL, and BITTER APPLE PILLS.
A Medicinal Compound expressly adapted for Females.
Price 1/1½, 2/9 and 4/6 per Box.

And again—

BOUTALL'S
LADIES' INFALLIBLE QUININE CONES,
2/6, 4/6, 10/- and 21/- per Box. Post free.

17, MARCHMONT ST., LONDON, W.C.
MENTION THIS PAPER.

We have already mentioned *English and Home Society* and we would point out to the editor and to the proprietor that Mr. Justice Darling not so very long ago expressed a forcible opinion as to the liability of those publishing such advertisements in newspapers.

Besides Boutall's advertisements we note those of Dr. Davis's Pills and Towle's Pennyroyal and Steel Pills. Although quinine cones are not used as abortifacients they are not preparations which any society, even *English and Home Society*, should use, and we may say the same of Damiana and Coca Rejuvenators which Boutall also supplies. As to the abortion preparations, it is obvious that the editor and the proprietor of the journal in question must either believe the advertisements concerning them to be true or not true. If the former, they are aiding and abetting a crime; if the latter, they are helping to obtain money under false pretences, which is also a crime. Now that this fact has been pointed out to them we have no doubt that they will see that such advertisements do not occur in their journal again.

MEDICAL CERTIFICATES FOR SCHOOL ATTENDANCE.

To the Editor of THE LANCET.

SIR,—Is a medical man entitled to charge a fee for giving a medical certificate for non-attendance at school: (1) when professional services are being given as Poor-law medical officer; (2) when as medical officer to a children's club; (3) when as paid medical officer to a dispensary? In the case of private patients there is no doubt the medical man is entitled to a fee. What should the fee be?

I am, Sir, yours faithfully,
J. P., M.D.

*** We do not think that questions such as the above have ever been legally decided, and the answer may in individual cases be expressed or implied in the contract under which the medical man attends the case. Subject to this we should say, however, that the answer to questions 1 and 2 is in the negative. As regards question 3, we think that a medical man in such a position would have no right to charge a fee unless there was some definite clause in the rules of the dispensary. In the matter of private patients again no definite rule can be given. We think that a fair fee to charge would be that of half the fee for an ordinary visit or consultation. For example, supposing that the ordinary fee is 5s., on being summoned to the child the medical man, if he gave a certificate as the result of his examination of the child would charge a fee of 7s. 6d., the additional 2s. 6d. representing the fee for the certificate.—ED. L.

IMPROVEMENTS IN ROME.

MR. MORGAN, the British Consul, in his report for the year 1905, just received at the Foreign Office, observes that people who return to Rome after an absence of a decade or so can scarcely recognise the old city under its modern garb which, however adversely it may affect its archæological interest, cannot but impress the visitor. Its population in the comparatively brief period of 20 years has risen from 345,036 to over 500,000; the extensive lands around Rome have given way to suburban quarters which, although unsightly, give shelter to thousands of newcomers from all parts of Italy, who contribute their share of individual labour towards the economic development of the city.

view of this fact and of the facts that the *mail carriers* between Chiromo and Blantyre had been held up by lions and that the construction of the Government ox-cart road from Katungas to Chiromo was *abandoned on account of the* presence *of* the tsetse fly, he would consider the advisability of calling, by telegraph, upon the Commissioner to report regarding the effect of the game preserve alongside the last-named township and to consider whether it could not be removed to some more suitable location.—Mr. Churchill *replied: I* have heard of some of the *reports* to which my hon. friend *refers; but* I cannot tell from any information in the Colonial Office whether they *may not* have been exaggerated. That any connexion exists between the appearances of lions, of the tsetse *fly*, and the *sleeping* sickness on the one hand and the *maintenance of the* game reserve on the other, is not at present established. But the Secretary of State is addressing the Commissioner upon the subject; and if it can be shown that the removal or contraction of the reserve would increase the health *and security of* Chiromo and its environs *instructions* will be *given accordingly*.

Tuesday, May 15th.

Royal Commission on Experiments on Animals.

Sir Philip Magnus asked the Secretary of State for the Home Department whether he was prepared to make any statement as to the appointment of a Royal Commission to consider the working of the Act under which experiments on animals were permitted for the purposes *of* medical research.—Mr. Gladstone answered: Yes, sir; in view of the fact that no inquiry into the subject has been held for 30 years it is the intention of the Government to recommend the appointment of *a Royal* Commission to examine the working of the Cruelty to Animals Act in the light of present scientific knowledge.

BOOKS, ETC., RECEIVED.

STRACEY.—On April 23rd, at Sutton Bonnington, Loughborough, the wife of Bernard Stracey, M.B., of a daughter.

DEATHS.

APPLETON.—On May 11th, at The Lizard, Cornwall, George Appleton, M.R.C.S.

GOULDER.—On May 9th, at Unthanks-road, Norwich, Frank Samuel Goulder, M.R.C.S., L.R.C.P. Lond., aged 50 years.

PEARSE.—On May 14th, Robert Edmund Pearse, I.M.S. (retired), aged 69 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

QUACKS AND ABORTION.

THE articles upon Quacks and Abortion which have appeared from time to time in our columns have had the effect of bringing about the disappearance of advertisements dealing with abortifacients from the pages of the better known and widely read newspapers. But in not a few journals we still find advertisements of a bad character. Some of these now lie before us in the advertisement columns of a paper called *Brighton and Hove Society* of March 24th. For instance—

BOUTALL'S LADIES' PINK REGULATORS
For Ailments Peculiar to Women.
A SAFE, CERTAIN AND SPEEDY REMEDY
FOR ALL OBSTRUCTIONS AND IRREGULARITIES.
Price 2/9 and 4/6. Extra strong, 10/- and 20/- per Box.

And another—

BOUTALL'S
STEEL, PENNYROYAL, and BITTER APPLE PILLS.
A Medicinal Compound expressly adapted for Females.
Price 1/1½, 2/9 and 4/6 per Box.

And again—

BOUTALL'S
LADIES' INFALLIBLE QUININE CONES,
2/6, 4/6, 10/- and 21/- per Box. Post free.

57, MARCHMONT ST., LONDON, W.C.
MENTION THIS PAPER.

We have already mentioned *Brighton and Hove Society* and we would point out to the editor and to the proprietor that Mr. Justice Darling not so very long ago expressed a forcible opinion as to the liability of those publishing such advertisements in newspapers.

Besides Boutall's advertisements we note those of Dr. Davis's Pills and Towle's Pennyroyal and Steel Pills. Although quinine cones are not used as abortifacients they are not preparations which any society, even *Brighton and Hove Society*, should use, and we may say the same of Damiana and Coca Rejuvenators which Boutall also supplies. As to the abortion preparations, it is obvious that the editor and the proprietor of the journal in question must either believe the advertisements concerning them to be true or not true. If the former, they are aiding and abetting a crime; if the latter, they are helping to obtain money under false pretences, which is also a crime. Now that this fact has been pointed out to them we have no doubt that they will see that such advertisements do not occur in their journal again.

MEDICAL CERTIFICATES FOR SCHOOL ATTENDANCE.

To the Editors of THE LANCET.

SIRS,—Is a medical man entitled to charge a fee for giving a medical certificate for non-attendance at school: (1) when professional services are being given as Poor-law medical officer; (2) when as medical officer to a children's club; (3) when as paid medical officer to a dispensary? In the case of private patients there is no doubt the medical man is entitled to a fee. What should the fee be?

I am, Sirs, yours faithfully,
J. P., M.D.

*** We do not think that questions such as the above have ever been legally decided, and the answer may in individual cases be expressed or implied in the contract under which the medical man attends the case. Subject to this we should say, however, that the answer to questions 1 and 2 is in the negative. As regards question 3, we think that a medical man in such a position would have no right to charge a fee unless there was some definite clause in the rules of the dispensary. In the matter of private patients again no definite rule can be given. We think that a fair fee to charge would be that of half the fee for an ordinary visit or consultation. For example, supposing that the ordinary fee is 5s., on being summoned to the child the medical man, if he gave a certificate as the result of his examination of the child would charge a fee of 7s. 6d., the additional 2s. 6d. representing the fee for the certificate.—ED. L.

IMPROVEMENTS IN ROME.

MR. Morgan, the British Consul, in his report for the year 1905, just received at the Foreign Office, observes that people who return to Rome after an absence of a decade or so can scarcely recognise the old city under its modern garb which, howsoever adversely it may affect its archæological interest, cannot but impress the visitor. Its population in the comparatively brief period of 20 years has risen from 345,036 to over 500,000; the extensive lands around Rome have given way to suburban quarters which, although unsightly, give shelter to thousands of newcomers from all parts of Italy, who contribute their share of individual labour towards the economic development of the city.

A British company is now going to give effect to a plan whereby the inhabitants of Rome will be provided with a summer resort placed in the immediate neighbourhood of the capital. The site chosen for the new summer town is called "Pratone," a small plain or table land, surrounded by shady woods of chestnuts, acacias, and oaks. The "Pratone" is 3210 feet above the sea level, and general local conditions are reported as being favourable for the carrying out of the object in view—short distance from Rome (21 miles as the crow flies), clear, bracing mountain air, the temperature in summer rarely exceeding 70° F., and cool, pure water. The company intends to run electric carriages between Rome and the "Pratone," which distance it estimates will be covered in an hour. The ascent to the "Pratone" will be effected by means of a series of steep inclines. The electric energy will be derived from the river Aniene at Tivoli. A large area on the top of the "Pratone" has been secured for the erection of a hotel and restaurant, as well as for a clubhouse, theatre, &c. The remaining land will be sold to private individuals who may wish to build summer residences thereon. In the neighbourhood of the "Pratone" there exists a spring of mineral water, most beneficial in cases of renal disorders. An electric tramway line connecting Rome with the surrounding villages has been opened to traffic. The advantages accruing to the population of the capital will be considerable, inasmuch as it is proposed to build houses for the less-favoured classes in the districts near Rome served by the projected line and thus to enable them to live out of the city where house rents have of late years increased very much owing to the dearth of apartments consequent upon the demolition ordered by the municipal authorities and the increase of population. The strenuous efforts during late years on the part of the Italian Red Cross Society to stamp out malaria in the Roman Campagna have proved most successful. The first attempt was made in 1900 when the returns showed that not less than 31 per cent. of the inhabitants of the "Agro Romano" had been fever-stricken. In 1901 the figure was returned at 26, 20 in 1902, 11 in 1903, 10 in 1904, and 5·1 during last year. Consequently there has been in five years a decrease of about five-sixths. These results were obtained by strict sanitary measures—use of wire nets so as to prevent the access of mosquitoes to cottages and free distribution of quinine among the peasantry. During the summer months a number of medical men belonging to the Red Cross Society take up their posts in the malarial districts in order to administer the necessary antidote as well as to show the people how to protect themselves from infection. The expenditure required for the effective operation of the organisation is partly paid out of the King's privy purse and partly by the provincial and municipal authorities.

THE MEDICAL TERMS OF THE EPISTLE TO THE HEBREWS.

To the Editors of THE LANCET.

SIRS,—The following quotation from Professor Schmiedel may be of use to your correspondent "M.D.," who writes in THE LANCET of May 5th, p. 1292: "'A medical language' was discovered in the Third Gospel and in Acts (so Hobart, 1882) and also in Hebrews (so Franz Delitzsch in his Commentary, 1857 (ET, 1868–70), condensed in the introduction to the second edition of Meyer-Lünemann)." With regard to what you say about the tradition coming from Clement of Alexandria I do not think that modern critics lay much stress upon its value. I believe it is more commonly held that the Third Gospel and Acts are from one pen (unknown), Hebrews from another (also unknown). That the writer of the former was the physician of Colossians, iv. 14, is unlikely (see Jülicher's "Introduction," Section 32), while for the latter a great number of names have been conjectured, two recent surmises being Apollos and Aquila and Priscilla.

I am, Sirs, yours faithfully,
M.B.

MOTOR CARS FOR MEDICAL MEN.

To the Editors of THE LANCET.

SIRS,—In answer to $Fe_2O_3(H_2O)_2$ I have driven a 4 cy. "Sunbeam," 1905 pattern, for the last 17 months. My expenses for upkeep without servant's wages or stable rent for the 12 months ending Dec. 31st, 1905, came to £155 12*s.* 8*d.* Incidentally I should advise $Fe_2O_3(H_2O)_2$ to think twice before fitting 810 × 90 tyres on a car such as he describes as he would find 815 × 105 tyres a big save in the end.

I am, Sirs, yours faithfully,
"234."

May 11th, 1906.

⁂ We may add that our correspondent writes from a very hilly part of the country.—ED. L.

◆

Justitia.—Bonds with assistants are not now so usual. A signed agreement setting forth the terms of engagement is all that is necessary, and a clause in this agreement might stipulate that the assistant should not, within ten years of termination of his agreement, practise within a limit of ten miles in the country, or one to three miles in a large town. Such a covenant has been upheld as reasonable in the courts of law.

Mr. John Hutton.—The triple wick candle ophthalmic lamp which was described in THE LANCET of Feb. 27th, 1904, p. 586, is made by Mr. Hawksley, 357, Oxford-street, London, W.

R. E. A. is referred to his medical adviser for the treatment of a trivial and common complaint.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (21st).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (3 P.M.).

TUESDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.).

WEDNESDAY (23rd).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9.30 A.M., Dental, 2 P.M.).

THURSDAY (24th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (2.30 P.M.).

FRIDAY (25th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), St. Mark's (2.30 P.M.).

SATURDAY (26th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

MONDAY (21st).—MEDICAL SOCIETY OF LONDON (11, Chandos-street, Cavendish-square, W.).—8.30 P.M. Annual Conversazione. Reception by the President. 9 P.M. Oration:—Prof. Kocher (Berne): Some Contributions to the Pathology of the Thyroid Gland.

TUESDAY (22nd).—ROYAL MEDICAL AND CHIRURGICAL SOCIETY (20, Hanover-square, W.).—8.30 P.M. Paper:—Mr. B. G. A. Moynihan: Report upon 232 Operations for Non-malignant Diseases of the Stomach.—Dr. H. French and Dr. H. T. Hicks: Mitral Stenosis and Pregnancy. (Epidiascope demonstration.)

FRIDAY (25th).—CLINICAL SOCIETY OF LONDON (20, Hanover-square, W.).—8.30 P.M. Papers:—Dr. F. Hawkins: Case of Thrombosis of the Abdominal Aorta.—Dr. C. R. Box: A Series of Cases in which Pulmonary Embolism was Due to Displacement of Pulmonary Thrombosis.—Dr. F. P. Weber: Acute Dilatation (Atony) of the Stomach and Intestines connected with Pneumonia and Pericarditis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (21st).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. A. Whitfield: Clinique. (Skin). 5.15 P.M. Lecture:—Dr. R. Saundby (Birmingham): The Dietetic Treatment of Dyspepsia.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M. Dr. Low: Tropical Medicine. Medical and Surgical Wards. 11 A.M. Operations in Out-patient Department. 12 noon. Dr. Low: Pathological Demonstration. Mr. Baldwin: Practical Surgery. 2 P.M. Medical and Surgical Clinics. 2.30 P.M. Operations. 3 P.M. Mr. Paget: Demonstration in Surgical Wards. 5 P.M. Dr. Saunders: The Examination and Treatment of Severe Cases of Gastric Ulcer.

CHARING CROSS HOSPITAL.—4 P.M. Dr. Waggett: Demonstration (Aural). (Post-Graduate Course.)

TUESDAY (22nd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. W. Harris: Clinique. (Medical.) 5.15 P.M. Lecture:—Dr. T. G. Stevens: The Necessity for, and Nature of, the Treatment of Backward Displacement of the Uterus.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—10 A.M. Medical and Surgical Wards. 11 A.M. Operations in Out-patient Department. 2 P.M. Medical and Surgical Clinics. 2.30 P.M. Operations. Dr. Abraham: Skin Diseases. Dr. Ball: Throat, Nose, and Ear Department. 5 P.M. Dr. Low: Tropical Medicine.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.).—3.30 P.M. Clinical Lecture:—Dr. J. Taylor: Paraplegia.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.)—4.30 P.M. Lecture:—Dr. D. Forsyth: Diagnosis of Abdominal Tumours.

ROYAL INSTITUTE OF PUBLIC HEALTH (37, Russell-square, W.C.)—5 P.M. Mr. W. R. Smith: The Law of Public Health. (Lecture V.)

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.)—5 P.M. Prof. W. Stirling: Glands and their Products. (Lecture III.)

WEDNESDAY (23rd).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—4 P.M. Mr. J. Berry: Clinique (Surgical). 5.15 P.M. Lecture:—Dr. H. Mackenzie: The Treatment of Acute Pneumonia.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—10 A.M. Medical and Surgical Wards. Dr. Ball: Throat, Nose, and Ear Operations. 11 A.M. Operations in Out-patient Department. 12 noon: Dr. Russell: Medicine. 2 P.M. Medical and Surgical Clinics. Dr. Beddard: Demonstration in Medical Wards. 2.30 P.M. Operations. 5 P.M. Dr. R. H. Cole: Puerperal Insanity.

CENTRAL LONDON THROAT AND EAR HOSPITAL (Gray's Inn-road, W.C.).—5 P.M. Demonstration:—Dr. Abercrombie: Nose.

ROYAL INSTITUTE OF PUBLIC HEALTH (37, Russell-square, W.C.)—5 P.M. Dr. C. Prausnitz (Breslau): The Bacteriology of Water, Milk, and Tuberculosis. (Lecture III.)

THURSDAY (24th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.)—4 P.M. Mr. Hutchinson: Clinique (Surgical). 5.15 P.M. Lecture:—Dr. P. Stewart: Trophic Nervous Diseases.

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—10 A.M. Medical and Surgical Wards. Dr. Low: Tropical Medicine. 11 A.M. Operations in Out-patient Department. 12 noon. Mr. Baldwin: Practical Surgery. 2 P.M. Medical and Surgical Clinics. 2.30 P.M. Operations. Mr. Dunn: Ophthalmology. 3 P.M. Dr. Hood: Demonstration in Medical Wards. 5 P.M. Mr. Keetley: Unreduced Dislocation of Shoulder and Elbow.

NORTH-EAST LONDON POST-GRADUATE COLLEGE (Tottenham Hospital, N.)—4.30 P.M. Lecture:—Dr. A. E. Giles: Obstructed Labour.

CHARING CROSS HOSPITAL.—4 P.M. Mr. Gibbs: Demonstration (Surgical). (Post Graduate Course.)

HOSPITAL FOR SICK CHILDREN (Gt. Ormond-street, W.C.)—4 P.M. Lecture:—Mr. Parsons: Phlyctenular Conjunctivitis and its Complications.

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.)—5 P.M. Prof. W. J. Sollas: Man and the Glacial Period. (Lecture I.)

FRIDAY (25th).—MEDICAL GRADUATES' COLLEGE AND POLYCLINIC (22, Chenies-street, W.C.).—4 P.M. Dr. StClair Thompson: Clinique (Throat).

POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—10 A.M. Medical and Surgical Wards. 11 A.M. Operations in Out-patient Department. 2 P.M. Medical and Surgical Clinics. 2.30 P.M. Operations. 5 P.M. Dr. Abrahams: Cases of Skin Disease.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Queen-square, Bloomsbury, W.C.)—3.30 P.M. Clinical Lecture:—Dr. J. Taylor: Paraplegia.

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.)—9 P.M. Mr. L. Hill: Compressed Air and its Physiological Effects.

SATURDAY (26th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.)—10 A.M. Medical and Surgical Wards. Dr. Ball: Throat, Nose, and Ear Operations. 11 A.M. Operations in Out-patient Department. 12 noon. Dr. Russell: Medicine. 2 P.M. Medical and Surgical Clinics.

ROYAL INSTITUTION OF GREAT BRITAIN (Albemarle-street, W.)—3 P.M. Prof. Sir James Dewar: The Old and the New Chemistry. (Lecture II.)

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and not to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 ar [illegible] which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to Advertisements; copies only should be forwarded.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 31, [illegible] Asnieres, Paris.

The Wightman Lecture

ON

CHRONIC APPENDICITIS AND THE EARLY DIAGNOSIS AND TREATMENT OF ACUTE APPENDICITIS IN CHILDREN.

Delivered before the Society for the Study of Disease in Children on May 18th, 1906,

BY AUGUSTE BROCA, M.D.,
PROFESSEUR AGRÉGÉ AT THE UNIVERSITY OF PARIS AND SURGEON TO THE HÔPITAL DES ENFANTS MALADES.

GENTLEMEN,—I could scarcely resist feeling a certain pride in speaking before you at this important meeting were I not called back to modesty by a more exact appreciation of the reality. For when you invited me to deliver this lecture, by which Mr. Wightman desires to perpetuate the memory of a son who too soon departed this life, I felt that I was indebted for this testimony of esteem to the circumstance that my Parisian colleagues had last year done me the honour of appointing me president of our Pediatric Society in Paris. As president of that society I had the pleasure to receive some of you (not numerous enough—allow me this reproach) when you came to Paris and visited our hospitals and great medical establishments. It is therefore to my French colleagues, through me, that your courteous invitation and appreciation are addressed. "Vous aviez d'ailleurs été les premiers, Messieurs les Anglais," by prompting us a few months before to proclaim medically our recent *entente cordiale*. With a great feeling of pleasure I personally saw the end of our secular rancours, which ought by mutual consent and a long time ago to have been immolated upon the altar of our common deity, Freedom. I am glad to have the opportunity of declaring here my opinion, for at that moment I was prevented from going to London, and I can assure you that it was not from any lack of sympathy with the movement.

Now that I have apologised for my unworthiness I must confess that I accepted your invitation with very great pleasure, but I should hardly venture to speak before you on such a common topic had not the first idea of lecturing on this subject come from your President, Mr. R. Clement Lucas, who had been struck when he visited my hospital wards by the great number of children operated on by me for appendicitis. He thought that it would be of interest to you if I related some of the observations which I had made during the past 15 years in children at an age when his own experience seems to suggest that this lesion is more frequent in Paris than in London. Some authors think that this frequency in childhood does not depend upon a true predisposition, the youngest being the most numerous amongst the population; the same proportion for a disease, whose real frequency is not modified by age, must give a larger number in the young. But that alone is not sufficient to explain the predominance found in Paris, where, so soon as appendicitis began to be carefully studied, important statistics were published founded on the experience obtained in our two children's hospitals, the cases being observed by the late Dr. Brun, by Jalaguier, and by myself. I will recall that in 1898 one of my pupils, Miss Gordon, took for the subject of her inaugural dissertation my first 78 cases of appendicitis in children, and since then I have operated more and more on patients under 15 years of age suffering from appendicitis, partly because we have learned to discover some cases formerly unrecognised, and partly also, it seems to me, because we have periods of increase due to the frequent returns of influenza to which we have unfortunately been liable since 1890. But if, as I understand from what Mr. Clement Lucas has written to me, the frequency of appendicitis in childhood is greater in Paris than in London, I do not think that influenza is the true cause of that difference, for influenza has now invaded all countries. If there is a particular cause my opinion is that it must be somehow connected with food.

In spite of some opponents, every day lessening, most medical men now consider that appendicitis is but the consequence, the localisation, of an entero-colitis formerly more extended. This localisation derives its surgical importance from the special anatomical connexion between the peritoneum and an intestinal appendix predisposed by its *structure to lymphangitic inflammation and even to perforation*. But it also seems that all forms of enteritis have not the same tendency to create appendicitis. Everyone knows how frequent gastro-enteritis is among babies not suckled and who, suffering from diarrhœa or constipation, insufficiently fed or overfed, end, according to the cases, in athrepsia, summer diarrhœa, or rickets. Appendicitis is, however, almost never seen in newly-born infants. The youngest on whom I have operated was 20 months old and *such an age is very exceptional. One of the causes of this* apparent rarity in infancy is, no doubt, the serious clinical difficulties we have to deal with; we are limited with very young children to an examination almost such as a veterinary surgeon might make on patients unable to give us any information unless by screams when our palpation gives pain. In this way the chronic forms, of which I shall speak to you by-and-by, escape us, and with them, no doubt, a great number of acute ones. But the fact is that our medical colleagues in their *post-mortem* examinations of nurslings who have died from gastro-enteritis never mention peritonitis of appendicular origin; they do not even describe the appendicular and peri-appendicular alterations whose importance we know well in older patients. This is partly owing to the fact that appendicitis takes a certain time for its development and for its surgical individualisation after the beginning of the causal enteritis; and I think that a few children who are attacked at the outset of childhood suffer from food badly digested. However, I do not believe this to be a rule and from the observations made at every age and in every country it appears that the general opinion of medical men is to the effect that an excess of flesh diet may be the origin of enteritis predisposing to appendicitis. But if English people eat a great quantity of meat when grown up, they are in the habit of giving little of it to their children during the first years of life—sometimes, perhaps, not even enough, if I may judge by what our French mothers call bringing up children *à l'anglaise*.

Among the predisposing varieties of enteritis there is one whose frequency has steadily increased of late years both in children and in adults. I mean muco-membranous enteritis and I invite particular attention to it, for some persons have supposed that there is a certain antagonism between that illness and appendicitis, but in my opinion this hypothesis is diametrically opposed to the actual facts. This point presents a double interest: firstly, for the diagnosis; and secondly, for the treatment. It is important as a matter of diagnosis, for I have seen some children die and others who almost died from repeated and unrecognised attacks of appendicitis because appendicitis in their cases was associated with evident attacks of muco-membranous enteritis; and those children's medical attendants, although of high professional standing, have sorrowfully learnt how wrong was the mischievous doctrine of antagonism. It is quite as important for treatment, for we are often obliged to subject our patients to medical and dietetic treatment for enteritis after their appendices have been removed. I am convinced that in every muco-membranous entero-colitis there exists an important nervous element. Some of them are purely reflex and disappear with surprising rapidity after the successful surgical treatment of disease of the abdominal organs, such as the kidneys, the uterus, the ovaries, &c. This may happen after the excision of a chronically irritated appendix; but the principal and most usual effect of such removal is the disappearance of long-standing and intense constipation due to intestinal atony from which many patients suffer before the operation. We do not obtain the same results in muco-membranous diarrhœa, and I am compelled to note the cases of patients who suffered from more or less serious relapses after the operation for appendicitis.

Clinical observation is not always able to determine with what certainty an operation would give relief in intestinal disorders; but if many times before the operation the symptoms were intense and prolonged it will be prudent after the surgical procedure to recommend that careful medical treatment should be continued for some months. I said that when enteritis exists appendicitis takes some time *to develop*, and I will now add that this process is very often a chronic one. Formerly we did not think so, for, struck by the acuteness of threatening accidents, we have not always looked into the antecedents of our patients for the indication of former chronic lesions, but we were not long before asserting that those symptoms existed and almost all of us now regard appendicitis as a chronic alteration aggravated by acute episodes. This notion has become common nowadays, but it was less common seven years ago, when I drew attention to it in a monograph on appendicitis. The distinction is important and if one is to study successfully all that concerns the diagnosis and the treatment one must separate carefully the two states which I have just mentioned—the chronic state and the acute crisis.

In order to explain things more clearly it is now usual to draw a comparison between appendicitis and inflammation of the throat, for we know that the initial lesion of the appendix—an organ which has a lymphatic tissue exceedingly developed—is a chronic folliculitis, comparable to that of the enlarged tonsils and adenoid growths; we know also that acute disease of the appendix may vary from a simple hæmorrhagic spot of folliculitis to the gravest gangrenous lymphangitis, states which are comparable to more or less violent attacks of acute tonsillitis or adenoiditis. And going farther in the comparison, I am of those who assert that if in both these kinds of cases the best treatment is by a surgical operation, in acute attacks it is prudent to let the inflammatory accidents subside before using the knife. My first care will be now to explain in what clinical ways chronic appendicitis reveals itself to us and what are our elements of diagnosis. It is not rare during post-mortem examinations or during various laparotomies to find evident lesions of the appendix in patients who had never been suspected of appendicitis. But perhaps these cases, whose symptomatology is really *nil*, would be more liable to exception if explained by their true cause—that is to say, by chronic appendicitis; some kinds of gastro-intestinal derangements, however, we are beginning to trace to appendicitis and to cure by appendicectomy.

In their common form such conditions are marked by gastro-intestinal atony, frequently attended with flatulent distension of the abdomen, by dyspepsia, by eructations, and by constipation, which is often obstinate, is sometimes interrupted by diarrhœal discharges, and may be caused by particular kinds of food. I have had under my care some patients who could not bear even milk and eggs and whom I was obliged to feed with vegetables only. These patients have, as a rule, the tongue coated, the breath offensive, the complexion greyish and even subicteric, a capricious appetite, and habitual nausea. It is not rare for them to suffer also from gastralgia or stomach-ache coming on without known cause and very variable in frequency, intensity, and duration. The patient feels a sudden, sharp, and not well localised abdominal pain, associated with sudden pallor and even a fainting sensation. It is easily understood, then, that in certain serious but exceptional cases the growth of children may be stopped by such digestive disorders and a real cachexy may be established. Certain patients who had for years been treated for obstinate dyspepsia, even for supposed intestinal and peritoneal tuberculosis, or (in the case of adults) for supposed intestinal or gastric carcinoma, were really suffering only from chronic appendicitis. However latent the local symptomatology of appendicitis may be it is generally found that a feeling of weight, an indefinite pain, or at least some degree of uneasiness draws attention to the right iliac fossa and on careful palpation we feel, under an abdominal wall normally depressible, the cæcum a little thickened and without flexibility, expanded with gases and gurgling; sometimes also a small tumour rolls under the finger and is due either to the appendix itself or to enlarged lymphatic glands, although nothing enables us to determine this point with certainty. Deep palpation, especially on McBurney's point, gives rise to a slight pain which can be recognised either by the patient's testimony or by a small defensive contraction of the wall. These local signs teach us to explain by something of ileo-cæcal origin the abdominal disorders observed; they exclude, for instance, some incomplete forms of nephritic or hepatic colic; but they may lead to error for they may be signs of a commencing tuberculous disease of the cæcum. We must not neglect this lesion, rare but puzzling as to its diagnosis, because it may break out with an acute crisis and even an iliac abscess. Once I have been thus mistaken when I thought to operate on a simple appendicitis after subsidence of the acute attack; on another occasion I saw a patient for whom another surgeon had opened an acute abscess which remained fistulous. I must confess that I cannot define here the elements of a precise diagnosis; at least in those cases where nothing of a tuberculous nature exists either in the abdomen or elsewhere, even when cæcal infiltration is advanced.

Until now I have spoken of a symptomatology always obscure. There are, however, cases or accidents more marked and manifested by special and paroxysmal phenomena, amongst which vomiting in variable forms seems to hold the first rank. We may observe, firstly, children who in the morning only frequently vomit their food, although they rarely vomit bile and do not show any rise of temperature. In certain cases these vomitings become habitual and so profuse as to be a grave hindrance to nutrition. I remember some children relatively young—between three and five years of age—who after an attack very variable in acuteness and form were unable to take any other food than vegetable broth. To some not quite compulsory vomitings may be added very different symptoms occasioning real difficulties of diagnosis. I remember a girl who suffered from obstinate constipation, headache, and retraction of the abdomen *en bateau*, so that one of my colleagues diagnosed tuberculous meningitis. Another patient, a boy, was, on the other hand, constipated with large meteorism, and another patient had acute intestinal obstruction with fæcal vomiting but without fever. However, he had only a paralytic reflex obstruction and two hours afterwards the opiates employed provoked the emission of gases and the end of every symptom. These patients recovered after removal of the appendix. In the main these cases constitute a series in which the symptoms of dyspepsia with gastro-intestinal flatulence are exaggerated either continually or by sudden attacks. Palpation and observations of the temperature prove that infectious phenomena are nearly *nil*. When an operation is performed we find sometimes some old peritoneal adhesions but more often we find none and the alterations are those due to simple chronic appendicitis. One can only see on the mucous membrane the hæmorrhagic stippling of one or two points of folliculitis.

In another series the infectious element becomes more important and a very frequent clinical form is the one where, although the initial dyspepsia may be very slight or even absent, there suddenly breaks out every sign of an *embarras gastrique fébrile;* sometimes after too plentiful a meal, sometimes without any appreciable cause, the child has an attack of indigestion with vomiting of food, the temperature very quickly runs up to 39° or 40° C., the breath has a the tongue becomes coated, and sour smell. At the same time he experiences abdominal pains which are localised either round the navel or in the right iliac fossa and on palpating this latter region you find some pain at McBurney's point, a slight muscular resistance, but no trace of phlegmonous infiltration. These last objective signs allow us to make a precise diagnosis if we are called in at the very moment of this slight attack and so we have learnt the great clinical value of *embarras gastrique* irregularly repeated in the previous pathological history of patients either suspected to suffer from, or really suffering from, chronic appendicitis. Beware of these frequent indigestions which mothers treat with an emetic or some other domestic medicine, when to the vomitings are joined a sudden fever and colic principally on the right side. Those accidents, even when not attended to, do not last more than one or two days. But in some cases they grow worse and more frequent, so as to present the classical appearances of the periodical acetonæmic vomitings of childhood. I have pointed out facts of that sort and have spoken of children treated during several years for such a disease by eminent medical men and restored to health only by the removal of their chronically inflamed appendices; I have also said that for that kind of patients it was very important to pay serious attention to the spontaneous pain or to the one excited by pressure on the right iliac fossa. I said also that for those patients it was necessary to trace the physical signs of chronic appendicitis, such as I have just described them. We shall acquire in so doing the elements of a sure diagnosis which is sometimes neglected. But I have not said or thought anything more on the subject and I have been very surprised to read in some recent papers on the matter that I considered always the periodical acetonæmic vomitings as a form of appendicitis. When these patients are operated upon it will be found that appendicular or peri-appendicular inflammations are, on the - - than in those of the first series, which average, more int have only dyspepsia with little or no rise of temperature. And here, with the ordinary folliculitis joined to an old sclerosis, we find sometimes *omental adhesions*; *but one may say that, with some exceptions, these changes do not require immediate surgical interference, however alarming* the symptomatology may have been. The impression produced in these cases, paradoxical as the statement may appear, is that of an acute symptomatology associated with a chronic pathologico-anatomical lesion, and certainly in these cases post-mortem examination will never cause the surgeon the regret of not having operated *rapidly* enough to anticipate the infection. Besides, if we examine thoroughly these patients' pulse, temperature, and functional indications of general or peritoneal infection, and if we ascertain at the same time the depressibility of the ileo-cæcal region under palpation, we do not find in these signs any indication for an immediate operation.

However, I shall not decide that the surgeon is never to interfere in these cases. Rather, on the other hand, I think that it is only to the surgeon that these patients should go, and it is convenient to state now the aphorism I shall soon fight for in another sense—namely, the aphorism "that there is no medical treatment of appendicitis." I admit that patients who suffer from *chronic appendicitis* and enjoy uninterrupted rest and take an exclusively vegetable diet may, if not cured, have at least no acute attacks and nothing save some insignificant uneasiness. But although that rest may be obtained for grown patients (exception being made *for the working class*), *it is impossible* to obtain it for children, especially *in the case of boys in* whom severe exercise, fatigue, articles of food *consumed surreptitiously*, and often some unknown cause, may readily excite grave attacks by which life is suddenly threatened from *peritoneal* or even general infection. And then is to be considered *the grave question*, *Must* the surgeon operate during the acute crisis? *In order to take*, I *do* not say an absolute and final, but a reasonable, *step we must first* consider the dangers we have to deal with. When an acute attack occurs in an appendix, whether it has or has *not* been already the subject of chronic irritation, the initial lesion *seems* to be the same as I have described above—namely, folliculitis, more or less intense, more or less limited. But from it may result a *real* lymphangitis, grave and diffuse, simple or gangrenous, *perforating* or not. Then the phenomena of general infection and *peritonitis*, which had remained at the second stage in the preceding *forms*, attain their full *development*. General infection seems to be conveyed especially through the veins. The origin of some cases of pyæmia with *predominant* hepatic abscesses is without doubt a pylephlebitis *starting* from the vermiform appendix. In other cases there is a true septicæmia, without any suppuration of the liver, which, however, undergoes fatty degeneration with extraordinary rapidity. The appendix is generally found to be *gangrenous* in these conditions but this is not an indispensable concomitant. Lesions are *found* which are sometimes so insignificant that after operation we have some *reason* to *think that in* reality we are in presence of a septicæmia, *originally* intestinal, where the appendix is unquestionably infected to a certain degree, but is involved only for a part and even for a very small part of it. These forms, which are *not* very well known to us yet, are *anatomically* and clinically very different from those in which accidents *special* to appendicitis depend upon the particular anatomical connexion between the appendix and the peritoneum. Then two principal *forms* are to be considered *according* as the peritoneal inflammation is or is not circumscribed by adhesions, for diffuse peritonitis, more or less septic, and encysted peritonitis ending by a localised abscess evidently have a very different prognosis. *The gravity of these* general or local infecting accidents is extremely variable. They stand between the slight attack with very sudden and transient high fever and those in which death occurs in two or three days. And it is easy to understand that these catastrophes haunt our memory, the more because the beginning of the illness does not always allow us to guess with precision what will be its ulterior evolution *Hence* arose the *opinion*, tempting because simple, that the *surgeon* must always operate in acute appendicitis as soon as he is called to give his advice. 12 years ago it was the opinion of almost all surgeons, myself included, and I am convinced that in acting as we did at the beginning of our practice we saved many lives. It was at a time *when our* surgical activity was checked by numerous *physicians*, reactionary leaders of medical therapeutics. By taking the general average of the statistics of various operators we arrived at a *mortality of about* 25 per cent. and in spite of some medical *statistics published* at the time I am persuaded that our *success was infinitely superior to that of our opponents. As they have become less and less numerous it is useless to* refute them now.

However, their assertions were partly true. Very often, after rejecting our recommendation of immediate operation, they obtained the resolution of what was formerly called perityphlitis and is now named appendicitis and on our part we became aware that for patients whose attack had passed off under medical treatment the operation performed in the interval between attacks, *à froid* as we say in France, was very much better. It allows easy removal of the appendix, which is not always possible amongst the adhesions of an encysted peritoneal abscess. It almost always enables us to obtain primary union after careful suture and so we avoid the hernia which is *so frequent after an abscess* has been incised. Moreover, it not only saves the patients *from these* ~~*two*~~ causes of a second operation more or ~~less delayed~~ but it also yields a reduced mortality of 10 per cent. instead of 25 per cent. in the hands of the same surgeons. We exclude, of course, operations for chronic appendicitis, the mortality of which is almost *nil*. I am speaking now especially of the acute cases that are brought *to* the hospital, including those which we see for the first time when *they are already* suffering from diffuse peritonitis and almost hopeless. I insist on that point because there is an important difference between private and hospital practice. In the acute attacks, with localised suppuration, we are liable to inoculate with the pus the adjacent *peritoneum* not *protected* by adhesions. Then follows a fatal peritonitis *and now we know* that a too early operation was the cause of this diffusion. *So a general* understanding was arrived at, or nearly *so*, *between the* members of our Surgical Society in Paris and the debate which took place in 1903 proved that almost all our colleagues, *renouncing the rule they had adopted in* 1899, had given up the *practice of always operating immediately*. They think now (and it has been my *opinion since* 1898) *that the rule must* be, Operate immediately if you are called within *the first* 24 hours following the outburst of the acute attack, but when you are called afterwards you must act according to the indications given by each individual case, and then with *the idea of calming* as much as *possible the* attack before operating. It is certain that the early operation, in the first 24 hours, before *perforation* or gangrene, before adhesions and suppuration, can be performed under anat*omical conditions* almost identical with those of the operation *à froid*, and nearly all the objections previously mentioned are then of no account. But in order to act in this way our diagnosis must be absolutely certain and in children this is difficult to obtain, in association with *certain clinical* features understood by all practitioners who are in the habit of attending or operating upon children, and this is the reason why they came to a general agreement about the subject The causes of error exist both for peritoneal and septic forms. When a child presents symptoms of acute peritonitis it is often more difficult to decide quickly in him than in an adult whether the appendix is attacked. Tubo ovarian inflammation *no doubt* conduces to error in the case of women but less than *pneumococcic* and gonococcic peritonitis in childhood, and we *must remark* that in a great majority of cases the pneumococcic *form attacks girls* and that the gonococcic cases are exclusively reserved *to them*. *The diagnosis* is generally easy when the right iliac pain is clear, *immediate, localised* and sharp, spontaneous or excited by pressure; when in a *few hours* the phlegmonous swelling with muscular *defensive contraction* of *the* abdominal wall is evident. But we must be cautious when children say that their abdominal pain is around the navel and when the swelling is relatively *slow* in forming. Besides that the pain limited to pressure with *muscular* contraction may also exist in the forms of peritonitis which I mentioned, for pneumococcic peritonitis is usually more or less encysted around the initial point, and gonococcic peritonitis starts from a tube, without, however, *any* tubo-ovarian tumour which could be found by rectal *investigation* as occurs in *women*. In gonococcic peritonitis the patient's *state* soon becomes *very* grave; the pulse is frequent, very small, and very weak; there is also cyanosis of the face; and these symptoms should attract *our* attention if the girl is suffering from vulvo-vaginitis. *But* at the commencement of pneumococcic *peritonitis*, save in the rather uncommon case of a previous pleuro-pneumonia, the nature of the case is quite uncertain and remains so up to the moment when pus is formed in the abdomen. As a rule, immediate diagnosis is impossible. On the other hand, it is certain that opening the peritoneum most seriously aggravates the virulence of the gonococcic infection; it also aggravates pneumococcic peritonitis just as much in an early stage before the formation of pus. The first of these two forms of peritonitis will never be amenable to surgical treatment; the second one will be but not in the initial stage. In fact, in both forms one may meet with serious complications if one tries exploratory laparotomy. On the other hand, laparotomy does not cause any injury in the beginning of tuberculous peritonitis simulating the beginning of appendicitis.

Another difficulty arises in children when symptoms closely resembling those of an appendicular attack, without iliac swelling, but accompanied with sudden fever and vomitings, are due to intestinal helminthiasis. In some of them the crisis ends after one or two days by the spontaneous evacuation of the ascarides. As early as 1893 I had one of these cases published by my pupil Jacob in his inaugural dissertation. These cases have been used to support the hypothesis that appendicitis may be provoked by intestinal worms. I believe this hypothesis to be unsound, but such facts must put us on our guard against performing an operation when we are not able to establish with precision an immediate diagnosis. Certain septic conditions without any peritoneal symptomatology but with pain at McBurney's point give rise also to mistakes. For instance, I see occasionally children who are supposed to be attacked with appendicitis and who are suffering in reality from pneumonia with an abdominal "stitch." This condition is easily diagnosed if the classical stethoscopic signs exist at the same time. But the perplexity is great in the case of a central pneumonia where the signs become manifest only after two or three days. These cases are not rare enough in children to give us a right to neglect them. Similar conditions also occur in association with pleurisy. Lastly, one must bear in mind, still more, I believe, in children than in adults, the possibility of typhoid fever beginning suddenly with vomiting, iliac pain, and even enlargement of the cæcum and its lymphatic glands. I have observed two cases, particularly obscure, where typhoid fever began in this way, though I knew that they were undoubtedly suffering from a previous chronic appendicitis.

My personal opinion and that of all my Parisian colleagues who are familiar with the treatment of the diseases of children is that these unavoidable doubts in diagnosis hinder us from adopting the rule (excellent in cases where the diagnosis is certain) of operating in every case within the first 24 hours. Again, we are ordinarily not called in soon enough for this because the small and slight attacks, which are by far the most common, are usually regarded by the mothers as indigestion and treated by them as such, so that when the medical man is summoned some time has been already lost and still more is wasted before the surgeon arrives. The opinion which begins to prevail is to the effect that when for one of the reasons stated we have begun waiting we must continue to do so, whilst studying from the moment we are summoned the clinical indications for an immediate, early, or postponed operation in each particular case. I think it useless to insist before you on the clinical phenomena which in diffuse peritonitis require immediate surgical interference—such symptoms as want of correspondence between pulse and temperature, green vomit, anuria, dryness of the tongue, alteration of the facial expression, and retention of the intestinal gases are all signs of diffused peritonitis or of peritonitis on the point of becoming diffused. We must except, however, patients brought to the hospital who are presenting these symptoms after a fatiguing journey and who feel themselves much better after some hours' rest. In these forms of diffuse peritonitis some surgeons, thinking the case hopeless, decline to operate and allow the patient to die. I believe that they are wrong, for now and then some cases judged to be hopeless have recovered after laparotomy. One might argue perhaps that peritonitis was not, in such instances, truly generalised. But the clinical fact remains that when the symptoms of generalised peritonitis exist recovery after a surgical operation is possible though exceptional. We must therefore operate without aiming at being able to show brilliant statistics. Encysted peritonitis must be operated on immediately only if an abscess has formed; in that case immediate operation is followed by remarkable success and we must not delay it if after the third or fourth day the fever persists and runs high and if there is swelling in the iliac fossa or beside the rectum. Further, without joining the few who advise waiting for fluctuation, we must come to an understanding about such cases. When in operating we find pus we must not conclude that the operation could not have been postponed until the day after, as has been said by many observers. For instance, in operating a long time after the subsidence of an attack we discover around an appendix sometimes calculous or even perforated remains of an abscess (caseous matter between adhesions); surely in these cases there has existed pus which has become harmless.

Things being so I have not been very surprised that in spite of the scientific precision of laboratory investigation the study of leucocytosis of the blood has led several observers to contradictory conclusions. We have in this condition a valuable indication but not the positive criterion desired by some surgeons and we must be content to associate it with the whole of the physical and functional phenomena of which I am going to speak in studying the cases in which we attempt to calm the attack. In doubtful cases we should inquire what medical treatment has been applied during the preceding days. In fact, it is sometimes astonishing how rapidly judicious treatment acts on patients who have been made worse by the use of purgatives and by inappropriate feeding. I consider it useless to give here particulars of what is meant by "medical treatment" in the acute attack. It may be recapitulated in few words: complete deprivation of food, only a few spoonfuls of pure water, and large bags of ice on the abdomen. In former times I always prescribed opium, now I give it only when specially required, when colic is very painful and not explained by an increase of the iliac swelling. I must especially draw your attention to the dangers of purgatives and must remark that patients who take milk or broth do not follow the regimen strictly. Patients thus treated must be carefully watched so that they may be operated upon, not only when the slightest appearance of peritonitis is noticed but also if the fever does not yield quickly and if the local swelling progresses. From all this it results that we should delay less when there is pelvic localisation of the swelling, a form difficult to watch and of which the diagnosis is made by paying attention to some special clinical facts, such as vesical pain in passing urine, and above all by systematically exploring the rectum with the finger. We must also remember that we are not to act in the same manner with patients who live in town as with those who live in the country; these latter almost always require to be operated on immediately. According to all these preceding facts there is no absolute rule to be always followed, but a good clinical observer will rarely allow himself to be surprised by peritonitis during an appendicitis with local swelling in which he watches an abscess in formation; and then disappointments will be less frequent than from diffuse peritonitis following an operation undertaken too late or from one performed too soon after the beginning of a peri-appendicular abscess and before the protecting adhesions have formed between the deeply seated pus and the anterior abdominal wall. The real difficulties of diagnosis and the painful surprises for surgeons are not due to these encysted peritoneal forms but to certain forms of gangrenous appendicitis in which diffuse peritonitis with vomiting of green or even black material (without doubt the final phenomena) occur; but in which, until that brutal and final outburst, peritoneal symptoms remain unheeded. The patient is dangerously infected, highly feverish, pale-faced, sometimes looking sub-icteric with cyanotic lips, but in the abdomen we do not find clear signs. The initial iliac pain draws attention to the appendix but I have not verified that it was from the beginning specially intense. In palpating the abdomen we do not find any swelling and we often cause but little pain; even the abdominal wall can be sometimes on all parts easily depressed when the appendix is in its normal place, *a fortiori* when it is hidden far away from our fingers in such a region as the top of the pelvis or in the lumbar fossa. During the operation we learn why no swelling was felt, as then we find around the gangrenous appendix very little pus and but very few soft adhesions.

Every one of us has saved some of these last patients by operating upon them immediately after the diagnosis was made. But all of us, also, have with some others failed to make a diagnosis during a certain period. First, because these cases being of a kind in which positive local signs are missing, we are uncertain as to the appendicular origin of the observed septicæmia; and secondly, because the appendix being incriminated it is very difficult to establish an early diagnosis between the gangrenous form which requires the immediate excision of the appendix and some other very septic form in which macroscopic alterations of the appendix are very slight and where it seems that the shock of laparotomy and the effect of the anæsthetic do harm by stopping, even for a short time, the hepatic and renal functions, already embarrassed by the sudden septicæmia. There are cases of grave jaundice with vomiting of blood in which the yellow atrophy of the liver seems to be the result of an appendicular folliculitis at first sight insignificant; the operation, even when performed at the beginning, as soon as our attention has been aroused only by a slight sub-icteric tinge, does not improve the progress of the disease. Now I have seen two of these cases—in grown-up patients I must say—with jaundice, fever, and rigors, that improved little by little, so that some weeks afterwards I removed a sclerosed appendix with traces of old folliculitis but without any trace of peritonitis around it. Therefore, especially in these cases, we remain doubting and sometimes we allow death to ensue while we wait. We may even in diffuse peritonitis accuse ourselves of having lost a favourable opportunity, but there is nothing to demonstrate that in operating earlier we should have succeeded better. Experimental as well as clinical study teaches us that the most rapid excision of an inoculated point does not stop infection if it is of a certain degree of virulence; the more so if we are aware of the inoculation only by local and general reaction in connexion with it, especially when so deeply situated an organ as the appendix is concerned. Those cases are happily very rare. The common cases are the peritoneal ones. For these, well treated, sometimes (I repeat it) an abscess will cause us to perform an immediate operation; we shall be rarely surprised by diffuse peritonitis if the patient is carefully watched; generally we shall succeed in calming the attack. It is well, then, to remove the appendix about a month after, if the attack has been slight. When the crisis has been grave we must wait longer according to the case. When I began to practise I thought with many of my colleagues that the operation was not necessary after a first slight attack. Now, on the contrary, we have all agreed about the necessity of operating after such a warning. A relapse is not inevitable but it is frequent, and we cannot guess how intense a new attack might be. For this reason we are right in saying that there is no medical treatment of appendicitis. When we do not operate immediately it is but to give time for the acute crisis to subside; then the operation is less dangerous. I have always said so and I now insist upon it because some authors—whose only excuse must be their complete ignorance of my writings—have described me as an obstinate abstentionist. You will also kindly allow me, in conclusion, to quote the phrase I printed in 1900: "The true question is to decide whether non-operative treatment is capable of calming a crisis when instituted well and in time; and whether it is better to try this treatment as often as possible, so as to replace the immediate operation by a delayed one. To that question I answer in the affirmative."

Before closing this lecture I must briefly describe what I think is the best technique for the operation. This account will be short because opinions agree save for some details.

1. Diffuse peritonitis requires, first, a long incision in the right iliac fossa, through which I think we must always try to remove the appendix. Almost always we must add to that first incision a median one, and often a third one in the left iliac fossa. The drainage must be very free, with very large indiarubber tubes going in different directions in the abdomen and the pelvis. Sometimes I wash out the abdomen with boiled water or physiological salt solution but I do not employ this method regularly because I am not at all convinced that it improves the always unfavourable prognosis of the operation.

2. Encysted suppurating peritonitis is treated as a simple abscess, by a large opening. No rule need be given; the incision is to be made where the abscess is situated, on the right side or on the left, in front or behind. There is a divergence of opinion as to the treatment of pelvic abscesses. Some authors teach that the best plan is to open them by rectal incision. It cannot be denied that these abscesses after abdominal incision progress often worse than the other ones. On the other hand, they sometimes heal spontaneously by discharging through the rectum; hence came the idea to imitate that natural method of evacuation. In spite of some successes due to that proceeding, I do not think that it ought to become general. I esteem it dangerous for the high-situated abscesses, which we must search for blindly, with special trocars, and as to the lower abscesses, which can be felt by the finger near the anus, they almost always can be drained through the iliac fossa—sometimes through the left one—where there are swelling and adhesions. It is very rare to find that the appendix goes directly downwards and that an abscess has collected in the pelvis whilst the iliac fossa is entirely free. But when it happens so, the rectal incision may be of real help. I remember, for instance, a girl whose iliac fossa I opened; I found the peritoneum here normal but a hemispherical arch of adhesions transformed the pelvis into a large purulent cavity. Judging the escape of pus into the peritoneum to be dangerous, I immediately closed the abdominal wall and opened the abscess by the rectal route. The patient recovered rapidly. After the spontaneous or surgical opening into the rectum, it is scarcely necessary to say that the appendix is not treated and frequently it gives no more trouble. Not always, however, for twice I have been obliged to remove it afterwards on account of persistent septicæmic disorders. The discussion as to what is to be done with the appendix in localised abscesses has to do with abdominal incisions. Some surgeons have advised its removal always at once. They say that it is the only sure way to stop the peritoneal infection around it and later to prevent such accidents as fistula, relapsing attacks, &c. But by breaking the adhesions and by inoculation of the serous cavity this method may cause post-operative diffuse peritonitis. In these cases I remove the appendix only when I see it easily under the adhesions and owing to my experience of these cases having extended I act in this way more and more often. I tie the appendix and cut it with the thermocautery; the cæcal wall is too much softened to bear a suture destined to bury the stump.

3. In the delayed operation, *à froid*, as we say, the *absolute* indication is to remove the appendix, and whatever may have been said it is always possible but not always easy. First, the appendix may hold in the abdomen various positions scarcely accessible when adhesions exist; secondly, because even when we can easily discover the appendix some difficulties and dangers may arise from adhesions and from relics of old purulent matter. We must be possessed with the idea that a positive diagnosis of this state is often impossible. It may happen that we feel in the iliac fossa the cæcum scarcely thickened or painful, yet in operating we find either behind the ascending colon and near the liver or in the upper part of the pelvis an adherent appendix surrounded by caseous matter.

For that reason I gave up the vertical incision known in Paris as "Jalaguier's" by which the appendix is removed through the aponeurotic sheath of the right rectus muscle. This muscular band lies afterwards opposite the sutured aponeurotic incision and prevents the occurrence of a subsequent hernia. By this method the removal of the appendix is very easy in simple cases but when we have to seek it deeply and when the cavity must be drained we expose ourselves to serious troubles. Therefore, after several attempts, and each time after cases where in operating I found unexpected difficulties, I adopted again the oblique iliac incision named "Roux's incision." But in this the muscles are divided and even after very good primary union a hernia is to be feared. Then I adopted finally the proceeding of McBurney in which after an oblique incision of the skin the muscles are not divided but separated between their fibres. The way to the ileo-cæcal region is very direct and if we meet with difficulties, with lesions calling for drainage, we can cut the abdominal muscles upwards or downwards and we have then all the advantages of "Roux's incision."

I have done now with these questions of technique; I could expound to you a general method but I should fear to become wearisome in detailing to you how to bury the stump or to close the abdominal wound. Moreover, I have already occupied your attention too long, whilst forcing upon you my bad English. You will forgive me, I hope, on account of my goodwill for having spoken myself instead of intrusting your secretary with my translation and the reading of it.

An Address

ON

DYSPEPSIA.

Delivered before the Cleveland Branch of the British Medical Association on Feb. 21st, 1906,

BY ALFRED G. BARRS, M.D. EDIN.,
F.R.C.P. LOND.,

PHYSICIAN TO THE GENERAL INFIRMARY AT LEEDS, PROFESSOR OF MEDICINE IN THE UNIVERSITY OF LEEDS, AND REPRESENTATIVE OF THE UNIVERSITY OF LEEDS UPON THE GENERAL MEDICAL COUNCIL.

MR. PRESIDENT AND GENTLEMEN,—The rapid rise and marked success of the operative treatment of organic diseases of the stomach of almost all forms is, perhaps, the most remarkable feature of the steady and irresistible advance which surgery has been making against abdominal disorders during the last 20 years and it has resulted, as we all know, in the transfer to the surgeon, so far as curative treatment is concerned, of, I think it may be said, the great majority of the cases of organic disease which in former times remained for weal or woe, to the end, in the hands of the physician. Whilst this transfer of work from the medical to the surgical side has relieved the physician of much that was unsatisfactory in the highest degree, consisting, as it did, of the prescribing of drugs and the ordering of diets, of which he had little but a purely empirical knowledge and with results which were for the most part disappointing to him and to the patient, it has, at the same time, very largely increased his responsibility in the matter of diagnosis and consequently in the advice which he should give as to whether surgical or medical measures should be adopted in any given case.

To the pessimistic physician it has at times seemed that surgery would very soon leave him without an occupation so far as diseases of the abdominal viscera are concerned, but so far is this fear from being realised that a notable increase in the number of those seeking a medical opinion may be observed directly traceable to the increased prevalence of surgical operations in the community. It may truly be said that Function is the special care and study of the physician whilst Structure is the special care and study of the surgeon. The physiological standpoint is the standpoint of the physician, the anatomical that of the surgeon. He who views disease of whatever kind from the anatomical or structural point of view very naturally seeks for an anatomical or mechanical basis or lesion to explain the disease, and he naturally sees nothing but a mechanical—that is a surgical—procedure for its cure. But we live and have our uses by function and not by structure, and our functions being good enough for our purposes we are very wisely quite indifferent as to our structure. The focal or anatomical view of disease and its eradication by surgery is, and always will be, the most attractive view both for patient and practitioner and very naturally so, and it is consequently not to be wondered at that it is extremely difficult for the surgeon as well as the patient to keep himself entirely free from a bias or prejudice in favour of the anatomical or surgical view of the malady in question and it is in supporting and strengthening the patient, and not infrequently the surgeon as well, against this natural but possibly dangerous bias, that the physician at the present day finds no small employment. If this is so it clearly behoves the physician so to equip himself that he may do his part with perfect justice both to the patient and to the surgeon; on the one hand striving that all mechanical conditions in the stomach which need it shall at the earliest possible moment have the advantage of that mechanical, surgical treatment which alone can be of any lasting service and, on the other hand, that all non-mechanical —that is, what we call functional—disorders shall be saved the pain, danger, and cost of ineffectual and unnecessary procedures. In former times, when a diagnosis could lead to nothing more than medicinal and dietetic treatment, no very great responsibility rested with us, for whatever wrong we might do we did not expose the patient to any greater danger or delay than that involved in ordering an acid when perhaps an alkali would have been better, or instructing him to take white meat instead of red, or to drink Vichy water instead of soda-water, or sending him to Harrogate instead of to Carlsbad. Now all this is altered and I say at once that a physician who wittingly, or unwittingly, wastes the time and resources of his patient in the medicinal or dietetic treatment of what he knows, or ought to know, is due to a detectible anatomical or mechanical condition in the stomach which only surgery can relieve fails in his duty to the patient and to himself, whilst he equally fails if he subjects his patient at the hands of a surgeon to a useless and therefore unjustifiable operation. It is in order to invite discussion on the relative frequency of the occurrence of cases of gastric disease, which an operation alone can cure, that I have taken "dyspepsia" as my text this evening.

The term dyspepsia is used by the lay public to cover every conceivable disturbance of digestion and every abnormal sensation that can be referred to the abdomen. With us it means nothing more than that the natural process of digestion is disturbed and no longer painless and pleasurable as it ought to be. The moment we have found a mechanical explanation for the disturbance in question the case ceases to be for us one of dyspepsia and becomes one of pyloric obstruction, gastric ulcer, carcinoma ventriculi, or what not. The term dyspepsia, if we continue to use it, should mean for us a disturbance of the digestion of food, which is due to a functional and not a structural defect on the part of the stomach—that is, a defect in its secretion or in its motility, or in both. My main purpose is to ask the question, Is such dyspepsia of frequent occurrence or does it indeed exist? My own belief, after a careful consideration of my experience, is that it is a very rare disorder, and that when abiding persistent dyspepsia or painful digestion of food is present it is most commonly due, if due to the stomach at all, to physical changes in that organ, which may or may not be discoverable on physical examination. I do not deny that dyspepsia in its slighter degrees is a very common ailment, but I venture to think that whenever it has reached such a degree of intensity as to become a matter for investigation by a medical man we should be very careful of our ground before we take up the position that it is due to functional disorder of the stomach.

Many gross and serious disturbances of gastric digestion are seen which are not dependent upon anatomical changes in the stomach but they are not therefore to be regarded as due to purely functional disorders of that organ. Indeed, I am prepared to say that by far the greater part of the cases of dyspepsia which I see, which are not due to organic changes in the *stomach are due to disturbances* outside the stomach altogether—are due, in fact, to blood states, circulatory disorders, intoxications, nervous diseases, &c.—that is *to say, given a normal supply of normal* blood and a normal state of the nervous system, the stomach, in the absence of organic structural changes in it or its orifices, *is no more likely to manifest* functional disturbances than the urinary bladder or any other hollow viscus, supposing its content to be of average normal composition.

I am no believer in wholesome food in its many varieties as a cause of indigestion. I am no blind prohibiter of tea, pastry, cheese, and pork in cases of dyspepsia. The infant who is fed on improper food (decomposing milk, &c.) and the man who drinks too much alcohol are both liable to gastr enteritis (that is, organic change) in varying degrees. T latter knows the cause of his ailment and can avoid it if l will. The former could and would, I believe, do the san if he could talk and were a free agent. When we allow ou selves to believe that ordinary articles of diet in ordinal quantities are a cause of dyspepsia, it is then that we are i the greatest danger of overlooking serious organic diseas The human stomach is by nature tolerant of—indeed, eag for—a mixed and very varied diet, and green apples, pork cheese, pastry, and tea are not abnormal constituent of it and, are not causes of disease. They do not al agree with everybody and *tastes differ, but we* are no to say on that account that they are causes of diseas and to forbid them to those who care for them. Foo is the *natural content of* the stomach and to believ that food is the cause of disease is just as dangerous to my mind, as to believe that cold causes peritonitis o that *open* windows are bad for consumption, or that puerperal fever arises from bad drains. I am not saying that the food content and structure being normal true functional disturbances of the stomach never occur. I only wish to state my belief that *they are so rare that they* should only be said to exist upon the clearest grounds. My firm opinion is that when dyspepsia of any severity or standing is present which can be shown not to be due to conditions outside the stomach there is great probability of its being due to organic disease of some kind in the stomach, even though it cannot at the moment be detected. How rarely one makes a diagnosis of dyspepsia in boys and how indiscreet they appear to us to be in the matter of food! They may occasionally vomit from excessive eating but for such moral delinquencies they do not naturally see a medical man. Whenever a boy is suffering from any substantial disturbance of digestion (and he very rarely does so) it will generally be found sooner or later to be due to organic disease either inside or outside the stomach.

There has been recently under my care in the Leeds Infirmary a man, 24 years of age, suffering from dilatation of the stomach due to simple pyloric obstruction. All the typical signs of this condition were present in a marked degree. A posterior gastro-enterostomy was done by my colleague, Mr. W. Thompson, and the patient left the infirmary in due course completely relieved of symptoms which had troubled him more or less for 12 years—that is, since his twelfth year—and his history is so instructive that I venture to bring it before you. When 12 years old he began to suffer from attacks of discomfort and actual pain after food lasting for periods varying in length from a few weeks to a few months, during which time he would be said to be suffering from dyspepsia and would be treated by various medicines and diets. Then for a few weeks or months he would be well and then another attack of "dyspepsia" would occur. The attacks gradually increased in length and the periods of remission gradually shortened until for the last two years he had never been free from distress more or less acute. At one time his stomach pains were relieved by food, a fact which many would say made one almost certain of the absence of organic disease. Then five years ago vomiting began and has been present in every attack since and when he came into the infirmary he had, as I have said, all the symptoms and signs of pyloric obstruction in a most marked degree and was reduced to an alarming state of emaciation and feebleness. It is impossible to escape the conclusion that this patient had been the subject of slowly increasing pyloric stenosis ever since his twelfth year and that he has waited 12 years for the only remedy—gastro-enterostomy. What various opinions must have been given and what various drugs and, above all, what various diets he must have suffered in those 12 years! No one was to blame; according to the views of 12 years ago he suffered from dyspepsia and was treated accordingly. With our present knowledge how difficult and even impossible it is to make a correct diagnosis in the early stages of the diseases of any internal organ and the stomach is no exception to this rule. Before the advent of physical signs in the abdomen—and these are to my mind the signs of paramount importance in the recognition of organic disease—by what means are we to distinguish between disturbances due to organic disease and those of functional origin? In trying to answer this question may I put before you a few clinical impressions which I have formed in the shape of propositions as follows? 1. Given the same symptoms in kind and degree, age and sex have an important bearing. In children (not infants) and adolescents stomach disorders due to organic gastric disease are very rare in males, less rare in females. 2. In young women stomach disorders are frequent and organic disease—e.g., ulcer—is common. In older females stomach disturbances not due to organic gastric disease are common but not more common than in males. 3. Whenever a man in middle life, who has hitherto had a good appetite and a good digestion, begins to complain of persistent loss of appetite and a painful digestion, the probability is that if the stomach is to blame it is the seat of organic disease. 4. Chronic vomiting, if due to stomach disorder, almost always means mechanical disease. 5. Any case of gastric disorder, which is associated with marked loss of flesh, is almost always organic. Anæmia, and above all cachexia, have the same significance. 6. Any gastric disorder which is seriously benefited by rest in bed and by restricted diet is probably of an organic nature. 7. Many cases of gastric ulcer in women have no physical signs except tenderness on pressure. Hæmatemesis would, of course, never be allowed to be due to dyspepsia alone.

If, then, such manifestations as pain excited by food, vomiting, hæmatemesis, with or even without (if that is possible) anorexia, wasting, pallor, and weakness, and which are relieved by rest in bed and restricted diet, almost always mean organic disease of the stomach, what symptoms worth mentioning are left to indicate functional disorders of that organ? Sensations of fulness and heaviness in the abdomen after meals, flatulence, acid eructations, pyrosis, borborygmus, deficient appetite, and constipation are the chief of the symptoms commonly mentioned by patients and discussed by writers as evidence of dyspepsia, and if after careful examination of the abdomen and all other regions and organs of the body we can find no evidence of organic disease we are then, I admit, justified in saying that the patient with such symptoms is suffering from dyspepsia—that is, a functional and not a structural defect of the stomach. That such cases are of common occurrence I beg leave to doubt. Such complaints are common and they are common in persons who present no evidence of organic disease in the stomach but are they common in persons who, while presenting no signs of organic disease in the stomach, can be declared to be of sound health in all other organs and so by the method of exclusion can be said to be suffering from functional disturbance of the stomach pure and simple? I am strongly inclined to answer this question in the negative.

Let me direct your attention for a moment to one of these symptoms, viz., flatulence, in order to show, as I think I can, that its least common causes are gastric disorder and errors in food. Flatulent distension of the stomach or a sensation of it (for it is not by any means always associated with actual visible inflation of the organ) is a very common and very distressing complaint, yet how rarely is it complained of by those who suffer from organic disease in the stomach, such as pyloric obstruction. Eructations, belchings, rumblings, borborygmi, are not always associated with flatulence, neither is pain. In its most typical and most distressing form flatulence consists in the sensation of extreme distension of the stomach by stagnant gas, such as we see very commonly in angina pectoris and other conditions of grave circulatory embarrassment, and I cannot doubt that flatulence even in its minor degrees is much more a circulatory than a digestive disorder. How constantly we hear sufferers from angina pectoris say that the moment the wind begins to move relief comes—that is, as soon as peristalsis is restored by the recovery of the circulation in the walls of the stomach the condition of angina and flatulence is at an end. How many cases of angina pectoris in their earlier stages are called dyspepsia because of this flatulence and are treated in the worst manner possible in consequence by diminished food, purgatives, and enforced exercise! I have long thought that a condition of the stomach in all respects analogous to the condition of the heart in angina pectoris—i.e., muscle failure due to impaired blood-supply and consequent distension—is a very real indication of circulatory weakness in elderly people and should be treated as such by food, stimulants, laxatives, and rest. Flatulence, such as I have described, is always relieved by food, never by restricted diet, just in the same way as borborygmus is relieved by eating and not by abstaining from food. I believe, then, that flatulence is much more frequently an indication of circulatory failure than of indigestion and that it is therefore much more likely to be improved by encouragement to eat ordinary solid food than by enforcing any restrictions.

There is another form of flatulence which I am sure is far more likely to be benefited by feeding than by starving and that is the flatulence of elderly people which comes on in the earlier hours of the morning, especially in those who take very little solid food after midday. Next to flatulence loss of appetite is perhaps the most important of the disturbances which I have mentioned as being referred to the stomach. I sometimes think that we fail to recognise the full significance of an enduring impairment or loss of appetite. A good appetite is just as sure an index of a normal state of health as a normal pulse, a normal temperature, and a normal respiration-rate, but because we cannot record it in figures upon a chart we are likely to forget it, but without it, it need hardly be said, health cannot be long secure. I do not think dyspeptics, in the sense in which we ought to use the term, suffer much from want of appetite. Any serious and abiding impairment of appetite usually means serious disease in the stomach or elsewhere. How rare a thing is pure functional anorexia ("anorexia nervosa") in the experience of any of us and how common is the complaint of loss of appetite! The chronic alcoholic has a poor appetite, especially in the morning, but he is suffering from chronic gastritis or hepatic cirrhosis—i.e., organic disease. How many and fatal mistakes have arisen from a belief in an idiopathic gastritis or a gastritis due to the ingestion of ordinary articles of diet? It is not so many years since a boy was admitted to the General Infirmary at Leeds suffering from a fatal peritonitis which was gravely attributed to the eating of two green apples and the post-mortem examination revealed a strangulated retro-peritoneal hernia.

My contention is, then, that primary functional disorders of the stomach, worthy to be ranked as diseases requiring much thought and care on our part, are comparatively rare and that when we are confronted with persistent gastric disturbances, however trivial in character they may appear to be, the possibility of their being due to organic disease in the stomach or to disease outside the stomach rather than to a purely functional disturbance in the stomach should be ever present in our minds. How often has it happened to many of us to make a diagnosis of dyspepsia when the event has shown that we ought to have detected organic disease in the stomach itself or some other disease such as Bright's disease, cardiac disease, blood disorder, lead poisoning, diabetes, tabes, malignant disease of the liver, cerebral tumour, or pulmonary tuberculosis, not to mention pregnancy and neurasthenia. One of the gravest errors we ever make in respect of this matter is to believe that repeated vomiting is due to dyspepsia.

The surgeon not infrequently seems to speak in a reproachful manner of the physician's inability to recognise with certainty grave organic disease in the stomach in its early stages and we shall readily admit that a trustworthy diagnosis of carcinoma ventriculi, for instance, in its very beginnings is a matter of the extremest difficulty, and it cannot but be helpful to us if we can legitimately hold a strong reservation against the probability of functional disease. I have already said that I regard careful physical examination of the abdomen and of all other regions of the body as of paramount value in the explanation of stomach symptoms. Dr. Hutchison, in a recent address on dyspepsia, has expressed his regret that investigations by means of test meals and the use of the stomach-tube have not as yet become popular in this country in the diagnosis of stomach disorders. I think it may safely be said that if such methods of investigation had been shown by those who use them most to be of any real value in doubtful cases they would long before this have been in the hands of all of us. My own experience of them leads me to say that I have not found them to be of service in any case where a differential diagnosis of organic and functional disease could not be made by simpler, more trustworthy, and more convenient means. No one, I imagine, would condemn any patient to cancer, or even ulcer, of the stomach on a chemical examination of the contents of the stomach alone. Such investigations can only afford us confirmation of opinions already-arrived at by the simpler method of diagnosis. If a careful consideration of the symptoms, physical signs, and effects of treatment does not enable us to arrive at a decision in any case where the question of malignant disease is seriously raised, the only trustworthy method open to us is exploratory incision of the abdomen. The good effects of rest in bed, suitable food, and the use of simple drugs such as laxatives and sedatives are to be observed in almost all cases of organic disease of the stomach, malignant or not; indeed, nothing is more impressive, I think, than the prompt relief which confinement to bed brings to all forms of vomiting due to mechanical causes—even cancer.

This therapeutic test, as it might be called, is not always to be relied upon, for one sees not infrequently a marked remission of symptoms and an improvement in health in cases of obvious malignant disease under treatment by rest and suitable feeding. The earliest stages of malignant disease we can never hope to detect except by direct inspection of the stomach. Even then errors are unavoidable, for have not most of us seen cases in which the surgeon has declared the lesion at the time of operation to be malignant and the event has shown it not to be so? My experience of this kind of thing has so much impressed me that I have made it a rule to urge abdominal section in all cases where a lump is to be felt in connexion with the stomach.

Having done what in me lies to show that any functional disorder of the stomach which can safely and truly be designated dyspepsia is probably a negligible quantity in gastric disorders, it is necessary that I should briefly refer to the concrete and definite functional disorders which are described by writers on these matters. Such disorders undoubtedly exist but I submit that they are great rarities. In the first place, a word about motor neuroses of the stomach. Many motor neuroses are described such as "hypermotility," "peristaltic unrest," and spasms and insufficiencies of the orifices—all these are probably purely hypothetical conditions apart from organic disease, but atony and atonic dilatation demand some attention. At one time I was a firm believer in what is called primary simple or atonic dilatation of the stomach, meaning by that a dilatation which could be demonstrated and which produced symptoms, notably chronic vomiting, and which was curable by washing out the stomach, rest in bed, and a suitable diet. Professor T. Clifford Allbutt has done much to secure the recognition of this condition in this country and it was through him that I became a believer in a dilatation of the stomach which was independent of pyloric obstruction or any other gross mechanical condition. Time and a more extended experience have led me to abandon, perhaps not entirely, this idea and I now hold that any dilatation of the stomach which can be demonstrated by physical signs and which is giving rise to vomiting is almost always due to pyloric obstruction. Many people have what may be called "splashy stomachs" at times but they are not necessarily dilated stomachs in a pathological sense.

Such definite conditions as gastro-succorrhœa, or Reichmann's disease, and gastroxynsis are, I am sure, very rare clinical conditions, and though many cases have been recorded, chiefly by continental writers, there is little or no reference to them in standard English works on medicine. Hyperchlorhydria, too, is, I believe, rare apart from gastric ulcer, in which it is readily recognised as a causative factor in the more serious anatomical lesion. Gastrodynia and gastralgia, pains referred to, but probably not residing in, the stomach are well recognised clinical conditions, but we hear of neither of them with anything like the frequency with which we hear of dyspepsia. There is one remarkable and distinguishing feature common to all these functional disorders of secretion and sensation and that is that all observers are agreed that they are best relieved by liberal feeding with solid food, especially proteids. Such articles of diet as veal, beefsteak, asparagus, black coffee, and Dutch cheese are included in Biedert and Langermann's diet table for patients with gastric hyperacidity.

And still my object this evening is not to persuade you that all diseases of the stomach of any importance can be cured only by surgical treatment. Many cases are still treated to a successful issue by the physician alone. It will be agreed at once that all cases in which a mechanical structural difficulty exists in the cavity or orifices of the stomach surgery offers the only hope of cure or permanent relief. In cancer of the stomach, wherever situated, operation affords the only means of permanent relief. Cases of chronic inveterate recurrent or multiple ulcer, with or without hæmatemesis, should, when medicinal treatment has failed after a reasonable and efficient trial, be treated by operation. Large numbers of cases of simple gastric ulcer in its less chronic form are treated successfully by rest in bed and ordinary medicinal and dietetic means. So are most cases of hæmatemesis due to gastric ulcer, and no case of simple ulcer should, in the first instance, be treated by operation, and in no case of first hæmatemesis is operation at once necessary or desirable. We can all call to mind many appalling cases of hæmatemesis in women which have recovered without operation and in which an operation at the moment could only have added to their danger. Hæmatemesis in men is so much more frequently due to duodenal than to gastric ulcer and duodenal ulcers so rarely heal without gastro-enterostomy that I always regard hæmatemesis in men as requiring much more serious consideration than in women. In any case of gastric ulcer, and especially in duodenal ulcer, in which vomiting persists and hæmatemesis is repeated after careful medicinal treatment, including long rest in bed, we should probably resort to operative treatment.

To my mind then, the indications for surgical treatment in stomach disorders are not difficult to determine and all cases which do not present those indications are to be left in the hands of the physician, and I think I cannot do better than bring this somewhat discursive paper to an end with a [illegible] other than surgical at our very few remarks upon th disposal in the treatment of such disorders and here again I am afraid I shall be found in a somewhat negative or even destructive attitude.

In the treatment of all stomach disorders diet still holds the foremost place in the mind of the patient and frequently also in the mind of the practitioner. I believe in stomach disorders, as in most others, that the patient's appetite and his experience are his best guides and I am usually content with ordering such patients such articles of ordinary diet as they like and which they find agree with them. I very rarely prohibit meat, or cheese, or tea, or pastry of any kind, and if the patient likes pork and it agrees with him I ask him to take it. I usually prohibit all alcohol, as well as all what I may call manufactured non alcoholic drinks, and I always enjoin the drinking of water in large quantities even at meals. The articles of diet against which I generally warn sufferers from gastric disorders (including ulcer of the stomach) are what are generally known as "slops," such as broth, soup, beef tea, and porridge, raw eggs (and indeed uncooked food of all kinds), jellies and "messes" and second cooked things, and all foods out of bottles, tins, and boxes. I am sure dyspeptics are better without sugar and sweet things generally. I am constantly seeing people who cannot take milk in bulk and I think it is far from being an ideal food for adults either in disease or health. It is certainly no more digestible than meat and what are called milk diets by their bulk and insipidity are very soon distasteful to the patient. In the same way I find that well-made pastry frequently agrees much better than the bulky farinaceous puddings. Cold meat, boiled or roasted, can frequently be taken when hot meat disagrees. No case of gastric ulcer can, or should, be treated except in bed. I am accustomed even in this disorder to abstain from ordering milk diet. If there is great pain after food, especially if there is hæmatemesis, I prohibit all food and give only water, and plenty of it, by the mouth. I do not believe in rectal feeding; it is very distasteful and sometimes painful to the patient and it is of no real value. I have seen the most troublesome and offensive proctitis set up by nutrient suppositories. Many cases of hæmatemesis have been treated successfully in my beds by absolute rest and the administration of plain fresh water by the mouth and nothing else, unless a very little morphine is given, also by the mouth, to relieve pain and restlessness. I rarely use the so-called hæmostatics but in deference to public opinion I have occasionally ordered such inert substances as chloride of calcium to be given in large doses, also by the mouth, and I have occasionally used adrenalin which is a powerful and active substance and should be given with care.

Of the drugs in common use in stomach disorders laxatives occupy the first place in my estimation and of them I believe rhubarb is the best. Our old-fashioned rhubarb mixtures consisting of rhubarb, soda, and peppermint are excellent things taken after food for what we call the chronic, middle aged, constipated, flatulent dyspeptic. Most of the official preparations of rhubarb, including the powder, are too pungent and nauseating. I find the concentrated infusion most agreeable and efficient. I am one of those who believe that constipation is a real evil and cannot be treated too persistently, so long as it is treated intelligently. The salts of bismuth hold a deservedly high place in all painful and irritable conditions of the stomach, including ulcer, and, of course, cancer, but the old-fashioned bismuth mixtures are not nice things to take and I am glad to find that the practice of giving carbonate of bismuth in large doses simply stirred up in water is now very generally followed. I do not think that morphine is often necessary, except, of course, in the pains of cancer, and in that case any dose which is necessary to keep the patient at ease should be given ungrudgingly. If the bowels are kept acting daily by means of rhubarb and the kidneys are kept acting freely with water I am accustomed to give morphine in any dose that may be necessary. When large doses are required I prefer to give it by suppository. Such things as lactopeptin and taka-diastase and other artificial digesters are for the most part as expensive as they are useless and therefore unnecessary

May I remind you that one of the most striking things we see in hospital practice is the astonishingly simple diets and medicines with which we manage to deal with our patients, and I believe just as successfully as with the more varied and expensive foods and medicines which so many think necessary in private practice, and it is from hospital practice that I have learned to believe in the simple foods and medicines to which I have referred. I apply to the dietetic management of the stomach disorders the same rule which I ventured to advocate some years ago in the management of typhoid fever—viz., that no further restrictions in diet should be imposed than loss of appetite and impaired digestion indicate—that is, that the patient should take what he likes of ordinary articles of diet in so far as he knows they agree with him. Bulk is of much more consideration than kind in deciding what food should be given in gastric ulcer and all other stomach disorders.

In saying what I have said about food in stomach disorders I have not intended to shock what I know are the firmly held convictions of many whose authority to speak in these matters is far greater than mine. I have tried to tell you as clearly and as frankly as I could the methods which I constantly practise and which I constantly advocate and which I have no reason to believe have fallen seriously behind other and more orthodox methods in the measure of their success.

PNEUMOCOCCIC PERITONITIS IN CHILDREN: A STUDY.

BY W. FRASER ANNAND, M.D. LOND.,
LATE RESIDENT MEDICAL OFFICER, EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL;

AND

W. H. BOWEN, M.S. LOND., F.R.C.S. ENG.,
PATHOLOGIST AND REGISTRAR, EAST LONDON HOSPITAL FOR CHILDREN, SHADWELL.

DURING the eight months in which we were working together at the East London Hospital for Children no less than four cases of peritonitis of the somewhat rare variety caused by the micrococcus lanceolatus came under our notice. The obscurity of the cases caused us to look up the literature on the subject, and the small number of cases reported in England and the slight attention which the condition has received in this country are our excuses for publishing the following account of the condition.

In 1885 da Bozzolo[1] described a case of infection of several serous cavities with numerous capsulated cocci in the exudate following on a nephritis. The case, however, was not fully worked out. In the following year Cornil[2] performed a necropsy on a case of pneumococcic peritonitis following pneumonia and associated with double empyema and pyopericarditis. During the next year or two isolated cases were here and there reported and in 1890 Nélaton[3] undertook the first operation for the relief of the condition in a woman, aged 32 years, but without success. Galliard[4] and Sevestre[5] also operated during the same year on cases of pneumococcic peritonitis, Sevestre's case being a child with apparently primary involvement of the peritoneum. This case recovered and remained well. On the continent numerous examples of the disease now began to be recorded, for the most part from France. In 1903 von Brunn[6] was able, in an excellent paper on the subject, to collect 57 cases of the disease in children and a further 15 adult cases. In the same year Jensen[7] of Copenhagen published a lengthy article on the disease and in this he discussed the affection very fully. These two papers are up to now the most important contributions to the subject. Since the date of von Brunn's paper, Matthews[8] and Bryant[9] have brought forward fresh cases and have written on pneumococcic peritonitis; other papers have been contributed by Quervain[10] and Ghon,[11] while cases have been reported by Panzacchi,[12] Brun,[13] Powell,[14] Taylor,[15] Waldo,[16] epigastrium the stomach resonance may practically always be elicited, even with the most advanced distension. With great swelling of the abdomen the veins on its surface may become prominent. During this stage the temperature is slightly elevated, the diarrhœa has ceased, and constipation may be present. Vomiting is uncommon. The patient usually wastes and in advanced cases the abdominal distension may offer a marked contrast to the general emaciation. On the other hand, the general condition sometimes remains good. The third phase is only present if surgical intervention has not been attempted or allowed and depends upon the natural endeavour to evacuate the abscess. This usually points about one month from the commencement of the illness and in most cases by this time the child is gravely ill, the cachectic appearance and distended abdomen often suggesting advanced tuberculous peritonitis. The usual site of perforation is the umbilicus Jensen states that in 25 cases of capsulated peritonitis perforation at the umbilicus occurred in seven and of eight similar cases following pneumonia the site of perforation was the same place in six. Perforation at other sites is rare, but the pus has been described as escaping through the vagina in several cases and through the bladder once.

After spontaneous evacuation a cure may result, but more commonly there is some retention of pus and the abscess has to be thoroughly opened and drained. Von Brunn emphasises the diagnostic significance of spontaneous fistula formation at the umbilicus: "It is so frequently an occurrence in pneumococcal peritonitis as to be one of the most characteristic features. If, after symptoms of an acute peritonitis in a child, a discharge of pus occurs from the umbilicus, pneumococcal peritonitis must be thought of first of all." With regard to the other signs and symptoms during this phase the temperature is usually low, œdema of the legs may occur, while vomiting and diarrhœa are absent; there may be signs of pressure, especially on the pelvic viscera. Von Brunn states that in his first case interference was decided against on the surgical side on account of the absence of fever. Our 91 collected cases include 26 cases of the primary circumscribed variety.

Passing on to secondary circumscribed pneumococcic peritonitis, it may be said that the signs and symptoms vary in their intensity and diagnostic clearness, according as the peritonitis sets in immediately after the onset of the primary manifestation or some days later. Among our 91 collected cases there are 11 cases belonging to this class. Of these 11 the first stage was unrecognisable in no less that seven (64 per cent.) owing to the peritonitis setting in very shortly after the onset of the primary affection which in six of the seven cases was either pneumonia or broncho-pneumonia, and in the seventh case an arthritis. In another case the first stage was also missed, although the primary affection was apparently less severe, being a peri-articular abscess followed by the involvement of the joint. It may be pointed out, however, that to speak of the primary lesion being less severe may not be quite accurate, since in some of the cases at least the primary affection may be merely the first local manifestation of what is in truth a pneumococcal septicæmia This general infection may in its severity be quite sufficient to mask to a greater or lesser extent the symptoms of the onset of the peritonitis. Of the remaining three cases (27 per cent.), in one the primary affection was pleurisy unaccompanied by pneumonia, the onset of peritonitis being well marked with pain, vomiting, and diarrhœa; in the other two there were broncho-pneumonia and pneumonia respectively as the primary lesions. An interval of some days elapsed and was followed by all the signs of an acute peritonitis. It follows from this masking of the acute symptoms that the majority of these cases were only recognised during the second or third stages which are the same as in the primary form and require no further mention.

Primary diffuse pneumococcic peritonitis is characterised by the acuteness of the onset, the severity of the symptoms, the rapid prostration of the patient, and in most instances his early death. In most of the cases reported its severity and early fatal result make it comparable with a perforative peritonitis. As mentioned above, the symptoms are those of the first or acute stage of the encapsuled variety but differ in their great virulence and persistence until the patient's death if no attempt be made to relieve the condition by laparotomy. Intense pain, vomiting, and diarrhœa set in suddenly, rapidly prostrating the patient, so that he speedily acquires the abdominal facies, with dry tongue, sordes, delirium, cold extremities, and cyanosis. The temperature varies between 100° and 102° F. and the pulse between 140 and 160. If no relief be afforded death soon follows. Of the 91 cases which we have collected 21 were of this primary diffuse form, including Nos. 4 and 16 of our cases.

Secondary diffuse pneumococcic peritonitis was present in 19 out of our 91 cases. Jensen, on the other hand, only found it once in 58 cases. Of these 19 cases the signs and symptoms pointed so strongly to the presence of peritonitis in five that an operation was performed. Of the remaining 14 in four there was strong evidence of the presence of peritonitis but as no operation was performed it must be allowed that the evidence was not sufficiently strong to warrant surgical interference. In three there were signs or symptoms pointing to abdominal infection but these were not sufficient to permit a diagnosis of peritonitis. In two there was no evidence of peritonitis before death, whilst in five either there is no clinical history supplied (2) or no reference has been made to the condition of the abdomen (3).

From this abstract of the 19 cases it will be noted that, as might be expected, when the secondary peritonitis is of the diffuse variety it gives definite early signs of its presence in a much greater proportion of cases than when it is localised—namely, in nine of the 19 cases (47 per cent). As further bearing on this matter it may be noted that amongst the 19 cases pericarditis was present five times, never as the only other local infection, but always in association with pneumonia, broncho-pneumonia, or empyema It may be said, in fact, that the presence of pericarditis is a sign of a severe general infection (septicæmia) and is associated with the most grave symptoms. Hence it is worthy of note that in the five cases where pericarditis was present at the post-mortem examination no mention is made of signs or symptoms pointing to peritonitis save distension of the abdomen in one case; indeed, in three of the cases it is definitely stated that no clinical evidence of peritonitis was forthcoming. We consider that this evidence corroborates the view that in the severe septicæmic type of case the local manifestations are obscured to such an extent as to prevent their recognition clinically. When peritonitis has been diagnosed the symptoms have been for the most part the same as those of the primary form, acute abdominal pain, sickness, diarrhœa, and abdominal distension. The antecedent lesion in these cases was single in ten and multiple in nine. In addition to four cases in which pleurisy or empyema occurred as the only lesion found post mortem accompanying the peritonitis the latter was also present in conjunction with other local lesions in eight cases and was nearly three times as frequent as any other local primary manifestation.

Pathological anatomy.—Jensen epitomises the action of the pneumococcus by saying "it is pus-forming and fibrinogenous." Our own experience is all in favour of this statement and a reference to the conditions found at the post-mortem examinations in our own cases will bear this out The pus, provided that no post-mortem infection from the intestine with bacillus coli has occurred, is odourless. Its fibrinous character is shown by the layer of lymph on the wall of the cavity and by the presence of jelly-like masses in the pus, this last appearance being due to an intimate mixture of the purulent and fibrinous elements of the exudate. The fibrinous layer covering the surface may appear simply as a layer of lymph, dull and whitish-grey, or, by the presence of pus in and between its layers, it may assume the form of a yellowish or greenish yellow gelatinous membrane which may usually be peeled away from the lining wall of the cavity. Sometimes it may be hæmorrhagic in character. Similarly, the main collection of pus, which is thick and yellow, or greenish yellow, may have floating in it the jelly-like masses mentioned, or flakes of lymph or hæmorrhagic masses, the last being due to the presence of blood between layers of fibrin. The above is the typical picture but in exceptional cases misleading characters may be found. In cases where the post-mortem examination has been deferred for more than 24 hours the exudate may be evil smelling owing to post-mortem contamination. This was so in Case No 4, reported below. In another case "the abdomen was full of thin, yellowish-brown pus which poured out as soon as it was opened" (Case 3). In both these cases, however, there was a very pronounced fibrinous element, and so constant is this character, so much a part of the action of the pneumococcus in a serous cavity, that Jensen has stated that the diagnosis can always be made on macroscopical examination of the pus.

The conditions found in the abdomen vary according as the peritonitis is diffuse or encapsuled. We can only speak from experience of the diffuse variety but give a synopsis of the accounts of other observers of the encapsuled variety. The local pneumococcic peritonitis of children, "the abdominal empyema" of Lennander, is usually subumbilical and rather more to one side than the other. Its limitations depend upon the early deposit of lymph shutting off the main part of the cavity of the abdomen. There may be more than one abscess. In a case given by Gailliard[23] one abscess lay between the liver and diaphragm and another one was situated around the spleen. Again, in Sevestre's[24] case one abscess was localised to the true pelvis and another to the cæcal region. If very large the abscess may fill the whole abdomen. In the first case given by von Brunn in his paper a large abscess had been opened, the pus pouring out under great pressure. He goes on to say, "the whole abdomen formed a huge abscess cavity in which the bowels, rolled into a little ball, lay almost like a foreign body. Liver, stomach, transverse colon, omentum, and coils of small intestine were all stuck together and lay in a mass as large as a man's head on the middle of the vertebral column." This is an extreme case. The serous membrane in these cases is injected, dulled, thickened, and covered to a varying extent with fibrin. Jensen believes that the encapsuled abscess begins as a diffuse peritonitis and its localisation depends upon early limitation by fibrinous exudate. Diffuse pneumococcic peritonitis was found post mortem in all our cases. A reference to Case 2 will supply the reader with a very good idea of the condition found in this variety. The condition of the serous surface varies with the length of time the abdomen has been infected. Exudation is usually rapid and deposit of fibrin takes place early. Although speaking from a very limited experience we believe that pronounced injection of the serous membrane does not take place early.

Passing on to the condition of the viscera we note that in none of our cases was any macroscopic lesion of the stomach or bowel found. The intestines, including the appendix, were carefully examined in all but with a completely negative result. In two cases some enlargement of Peyer's patches was found. In each a single Peyer's patch was removed and a portion of the spleen at the same time. These were microscopically examined for organisms. One proved entirely negative but in the other Gram-positive diplococci morphologically identical with the pneumococcus were found both in the Peyer's patch and in the spleen. It must be clearly noted that in this case there was no trace of ulceration, the mucous membrane was not notably injected, and the organisms which we look upon as pneumococci were not found deeper than the mucous membrane of the Peyer's patch.

On leaving this division of the subject a few lines may be written upon the bacteriology of the cases we report. In two of our cases (Nos. 1 and 3) we relied upon the presence of Gram-positive diplococci, either alone or in chains, scattered in large numbers throughout the pus, this diplococcus being morphologically identical with the pneumococcus. In one of these cases the pneumococcus had already been grown from pus taken from the pleural cavity (Case 1). In another case (Case 2) we added to the evidence supplied by the examination of the pus the further proof mentioned above—namely, the presence of pneumococci in the spleen and a Peyer's patch. In Case 4 we cultivated from the blood, growing a Gram-positive diplococcus morphologically identical with the pneumococcus. Dr. J. W. H. Eyre, bacteriologist to Guy's Hospital, kindly examined this culture for us and stated that it gave a typical growth on blood agar but that inoculation into a rabbit did not kill the animal. Of our other cases quoted at the end of this paper, in seven the proof was either the presence of the pneumococcus in cultures from the blood or its presence in the peritoneal pus. In the other five the evidence is indirect, pneumococci being found in pus from an empyema or pyopericardium, and as macroscopically the peritoneal pus was similar in nature the conclusion was drawn that the same organism was the cause of the abdominal pus.

Diagnosis.—Michaut[25] has stated that whereas the diagnosis has frequently been made in the encysted form it has only once been made in the diffuse form. This statement is set down as an appropriate introduction to the discussion of diagnosis, since in most cases encysted peritonitis can be diagnosed, whilst the diffuse may, and probably in the majority of cases will continue to be, extremely difficult if not impossible to diagnose correctly. The importance of the history is very great in many of these cases. This may be of the greatest diagnostic value, or its true meaning may only be recognised after the event. Experience has shown how obscure pneumonia may be in some cases, much more so a tonsillitis or conjunctivitis due to the pneumococcus. We recently saw a case of fever lasting over a week and falling by crisis, in which all the pulmonary signs recognised by skilled observers pointed to diffuse bronchitis only. Typhoid fever was thought of, but Widal's reaction proved negative. After the fall of temperature the patient expectorated a muco-pus which was examined for tubercle bacilli; these were absent but numerous bacilli and diplococci were present. The diplococci were Gram-positive and morphologically identical with the pneumococcus and we are of the opinion that what might have been a very obscure case but for this examination was a case of central pneumonia giving practically no physical signs of consolidation. This case occurred in an adult, but similar cases occur more frequently in children and we are inclined to look upon "cough and fever" preceding pneumococcic peritonitis as being highly suggestive of a previous pulmonary infection. In this connexion we may call attention to the second of our own cases where the boy had an abscess about the hip. This abscess was opened but unfortunately no bacteriological examination made of the pus. Looking back now on the case we consider that this inter-muscular abscess was the primary lesion and would emphasise the importance of a bacteriological examination in such cases. At a later date a baby was admitted into the Children's Hospital at Shadwell with several superficial abscesses which were opened. An examination of the pus showed the presence of pneumococci and we therefore drew off a sample of the blood from the median basilic vein and on blood serum pneumococci grew in pure culture. We would lay special stress on history in these cases and as being especially valuable when forthcoming in a case of acute peritonitis setting in suddenly and in an apparently previously healthy child. When the difficulty of diagnosis is considered and the heavy mortality necessarily resulting, no clue, however slight, can be disregarded.

The localised form of peritonitis will, as Michaut says, be diagnosed, since sooner or later an abdominal abscess will form, but unless the history of the acute attack or, in some cases, of a preceding pneumococcic affection elsewhere is obtained the diagnosis of the abscess may not be made until it is on the point of bursting at the umbilicus. This is unsatisfactory, for it means that the child has been subjected to a continued infection for a long period, at times up to a month and in many cases is in a weak and emaciated condition before the surgeon operates. The diagnosis should be made, if possible, and the condition relieved during the acute stage or during the early part of the quiescent period. The cardinal symptoms to rely upon are the acute onset of the vomiting and diarrhœa and abdominal pain, associated with a sudden rise of temperature. Herpes labialis appears to be so uncommon that its absence is quite unimportant, but it has occurred in a few cases. This local form of the disease has to be diagnosed from other forms of peritonitis, including that following appendicitis, from typhoid fever, and in its second and third stages, from tuberculous peritonitis.

From other forms of peritonitis which, save for that arising primarily from the appendix, are uncommon there will be great difficulty in diagnosis in the absence of any history. The same may be said with regard to the diagnosis from appendicitis, since the pain is chiefly in the right iliac fossa in many of these cases, while in many cases of appendicitis, especially in the early stages, the pain is not localised. Further, in very young children knowledge as to the situation of the pain is often unobtainable. In many such cases operation will be withheld and expectant treatment adopted. It is of importance that in such cases the second period should not be missed but the abscess formation treated as soon as recognisable. From typhoid fever the diagnosis may prove difficult if diarrhœa persists after the vomiting has ceased and the temperature remains raised. The absence of the rash and of splenic enlargement, the presence of a leucocytosis as opposed to a leucopenia, and the fact that a Widal examination proves negative, are all points against the illness being typhoid fever. There can be no doubt that in the many cases of encysted pneumococcal pus have been looked upon as cases of tuberculous peritonitis. It is somewhat remarkable that on looking through the reports of cases at the East London Hospital for Children for the last ten years not a single case of intraperitoneal abscess due to the pneumococcus, operated upon and cured, has been recorded as such. We are of the opinion that such cases must have been treated but, the pus being looked upon as tuberculous, no bacteriological examination was made. There can be little doubt that in the later stages, when the child is very emaciated, the appearance is almost typical of tuberculous peritonitis. As points in diagnosis von Brunn calls attention to the importance of a history of the acute stage and the fact that in tuberculous peritonitis masses can be felt which are absent in the pneumococcal form. In the chronic stages he says only puncture can decide the question.

[23] Loc. cit.

[24] Loc. cit.

[25] Loc. cit.

The diffuse form of pneumococcal peritonitis has to be diagnosed from a severe and acute attack of typhoid fever and from peritonitis following perforation of a viscus. The same emphasis may be laid on the importance of history in this form as in the local, but with the primary form there is little doubt but that in most cases the diagnosis will be next to impossible. We have no statistics at hand with regard to the relative frequency of acute diffuse peritonitis due to the pneumococcus and that due to perforations of the bowel. Such figures will no doubt be supplied in the future and prove valuable. For the present we can only say that as the commonest causes of acute perforative peritonitis in children appear to be perforation of the appendix and typhoid and tuberculous ulcerations of the bowel, in the absence of any history one of these conditions will still be diagnosed, but that if the peritonitis is recognised and an operation follow the character of the pus should lead to a diagnosis in most cases at once. Jensen in his paper states that of 16 cases of operation on the diffuse form eight were operated on for appendicitis.

Prognosis.—It appears to us on looking through the collected cases that prognosis depends on three factors: (1) whether the peritonitis is local or diffuse; (2) whether an operation is or is not performed and, if performed, whether or not at a suitable time; and (3) the previous presence or the onset of a severe complication. Whether the peritonitis is primary or secondary, providing there is no other complication, does not appear to affect the prognosis to any material extent according to our table. The following is the table which speaks for itself:—

Variety of peritonitis.		Number of cases.	Number of cases operated on.	Number of cases not operated on.	Result.		
					Recovery.	Death.	Uncertain.
Primary local		26	26	0	22	3	1
Secondary local ...		11	10	1	9	1	1
Primary diffuse ...		21	10	11	2	19	0
Secondary diffuse ...		19	5	14	3	16	0
Origin uncertain	local ...	8	8	0	6	2	0
	diffuse ...	6	3	3	1	5	0
Total		91	62	29	43	46	2

45 of the 91 cases had encysted peritonitis, of which 44 were operated on, and of these 37 recovered and six died; in two the result is uncertain. The other 46 cases were of the diffuse variety, of which 18 underwent operation. Of the 18 cases operated on six, or 33·3 per cent., recovered, whereas all those not operated on died. The one case of the local variety not operated on recovered by spontaneous evacuation of the pus. The above table shows that recovery occurred in 86 per cent. of those with the encysted form, whilst only 14 per cent. of the cases with the diffuse variety survived.

Treatment.—In dealing with treatment we shall be very brief, simply giving the conclusions arrived at by a study of the cases reported and a consideration of the pathological condition found at post-mortem examinations. There can be no doubt but that when once pneumococcal peritonitis has been diagnosed a laparotomy should be performed. Jensen says, "Operate before a distinct abscess has formed," but acknowledges that the early stages may be very difficult to diagnose. Remembering, however, that there is an acute stage in localised pneumococcal peritonitis in which the indications for operation may not be strong enough to lead to immediate intervention, it may be hoped that in the future such cases may be watched and the persistence of fever, of some abdominal tenderness, and perhaps diarrhœa, may lead to an earlier diagnosis of the condition and earlier operation. At operation the cause of the peritonitis may, in the great majority of cases, be recognised by the character of the pus, non-odorous, greenish, and fibrinous. It is sufficient in the localised form to treat the abscess in the simplest way, inserting a large drain and allowing it to heal from the bottom. With the largest of abscesses there is no trouble. In the acute diffuse form the abdomen will be opened in many cases for peritonitis of unknown cause. The character of the pus should make the diagnosis clear. It is as yet impossible to advise any exact line of treatment but, if the pus is not evil-smelling, mopping out the cavity and closing it without drainage would appear to be the wisest course. In the event of the pus being foul-smelling from infection with bacillus coli the perforation of some viscus would suggest itself and this would resolve the treatment into that special to perforative peritonitis.

Summary.—1. Pneumococcic peritonitis is a comparatively rare disease in children but in the past many cases have not been recognised. 2. It is in about a third of the cases secondary to some remote pneumococcal lesion; of these affections of the lungs and pleuræ are by far the commonest, the middle ear being the next most common site. The infection is carried to the peritoneum in the blood stream. 3. In the remaining two-thirds the peritoneum is probably infected from the bowel in the vast majority. No microscopic lesion is, as a rule, found. 4. In half the cases the pus is encysted; in these the diagnosis is fairly easy, the prognosis is good, and the treatment is laparotomy and drainage. 5. In the other half of the cases the peritonitis is diffuse, the diagnosis is very difficult, and the prognosis very gloomy. The treatment is laparotomy. 6. The pathological appearances are characteristic.

The cases which we personally observed and for permission to publish which we are indebted to the medical and surgical staff of the East London Hospital for Children were as follows:—

CASE 1.—A boy, aged four years, was brought to the hospital in March, 1905, with the history that seven weeks before he had had tonsillitis, followed by pneumonia. This got better after 14 days, but on the sixteenth day he had a relapse. He had since been getting worse and latterly had had some pain in the chest and abdomen. The boy on admission was pale and thin and had great dyspnœa. The left chest was obviously full of fluid and a piece of rib was resected, a pint of pus, creamy and odourless, escaping. Great improvement in the boy's condition followed the operation. During the next week the temperature was irregular, occasionally reaching 101° F. at night. On the ninth day after admission he was worse and suddenly became very collapsed, but revived on receiving stimulants. On the eleventh day he had two similar attacks. There were slight impairment of resonance and deficient breath sounds at the right base and the general condition was worse. During all this time the empyema which had been opened was draining well. On the thirteenth day the breath sounds at the right base were stronger and the general condition was unchanged. On the fifteenth day the patient looked much worse. The right limit of cardiac dulness, which had been extended to the right by the fluid in the left chest and had never recovered its normal position, was two inches from the right edge of the sternum and there were marked dulness and resistance at the right base behind. The question arose as to whether there was a right-sided empyema or a purulent pericarditis. The child died before the arrival of the visiting physician.

At the necropsy the right pleural cavity was found to be obliterated, save for a small pocket behind and at the base which contained from one to two ounces of thick greenish pus. The left empyema had been drained perfectly. There were firm adhesions between the pleural and pericardial surfaces. Pyopericarditis was present, with a thick layer of lymph on both visceral and parietal surfaces. The mitral valve showed old endocarditis. There was myocardial degeneration. On opening the abdomen general diffuse peritonitis was found. There was a pocket of pus between the liver and the diaphragm, just to the right of the coronary ligament. The other organs were normal. Films of the pus from the abdomen showed diplococci morphologically identical with the pneumococcus. The pus from the empyema grown on blood serum gave a Gram-positive diplococcus indistinguishable from the pneumococcus.

CASE 2.—A boy, one year and five months old, had a swelling over the left trochanter which the mother had noticed four days before. On examination the child was found to be a small wasted infant; the temperature was 101·6° F., the pulse was 156, and the respiration was 40. There were no physical signs in the chest. There was a large fluctuating swelling of the size of a man's fist over the left trochanter; the skin over it was reddened. Next day the abscess was opened and the pus evacuated. No communication with the hip-joint could be found. Three days later, as the temperature had not fallen at all (it was then 104°),:the abscess cavity was explored under an anæsthetic and one or two small loculi were opened up. These ramifications of the abscess cavity penetrated the intermuscular planes of the buttock in all directions. Counter incisions were freely made. That evening the infant began to vomit and diarrhœa set in. Next day the vomiting and diarrhœa continued; no cause could be found and the child died on the following morning.

At the necropsy the lungs were tough and fibroid, possibly the late results of a pneumonia. At the lower and posterior part of the right pleural cavity there was a trace of pus between the pleural layers which were coated with lymph. The left chest, the heart, and the pericardium were normal. The abdomen was the seat of a diffuse peritonitis. The pus was thick, greenish in colour, and very rich in fibrin. The peritonitis seemed to be most pronounced around the cæcum and the ascending and descending colon. A small shut-off collection of pus was situated between the ascending colon and the cæcum on the outer side and the spine on the inner side, the mesentery and the small intestine bounding it in front. There was lymph on the under surface of the diaphragm. The intestines were normal, as were the liver, the spleen, and the kidneys. There was slight enlargement of the mesenteric glands. The abscess in the left hip was extra-articular and unconnected with bone. No diseased bone could be found. Films of pus from the peritoneum yielded a Gram-positive diplococcus morphologically identical with the pneumococcus. The same organism was found in sections of the spleen stained by Gram's stain and Bismarck brown and in the mucous membrane of a Peyer's patch, of which sections were made.

CASE 3.—A male infant, one month old, was brought to the hospital with the history that three days before he had suddenly been seized with sickness. Previously he had been healthy and had been fed on the breast only. The first day of his illness he had vomited three times and diarrhœa set in on the next day. On the morning of his admission patches of redness were seen all over the body. The child was very wasted, erythematous macules and papules covered the body, the abdomen was greatly distended, and large veins were coursing over the surface. The skin was dusky. There were severe vomiting and diarrhœa. The temperature was 100° F. on admission. The child died in three hours, the temperature having risen to 103°.

The necropsy showed congestion of the lungs; otherwise the thorax was normal, as were the brain and ears. The abdomen was full of thin, yellowish brown pus, and in places there were quantities of semi-solid, greenish, jelly-like pus. Peyer's patches were a little swollen but there was no ulceration of the bowel. The liver was somewhat fatty but the other organs were normal. Pus from the peritoneum stained by Gram's stain and counter-stained by Bismarck brown showed numerous Gram-positive diplococci morphologically identical with the pneumococcus.

CASE 4.—A girl, aged five years, had had nausea and pain round the umbilicus ten days before admission, with difficulty in micturition, but no scantiness of urine. She had previously been quite well and had never had scarlet fever. There had been a little vomiting for two days. Seven days before admission the feet and legs began to swell and the swelling had been since increasing and spreading upwards. The bowels had been constipated. On the morning of admission redness of the legs and thighs was noticed. On admission at midnight she was seen to be a well nourished girl. The face was pale, not puffy, and there was no appearance of facies abdominalis to be noted. The mucous membranes were of good colour but the tongue was very foul. The patient complained of severe pain all over the abdomen. There was great œdema of both legs, of a slightly solid character, which extended upwards in the abdominal wall rather more on the left side than on the right. The skin over the lower part of the abdomen and the thighs was red in patches. The temperature was 102° F. and the pulse was 145, not running. There were no physical signs in the chest. The abdomen was considerably distended and moved fairly well with respiration in the upper part and a little in the lower part. There was much general tenderness but the appendix region could be easily palpated and no thickening was felt. There were no dulness in the flanks and no signs of fluid. A catheter was passed and a small amount of urine was drawn off which was loaded with albumin. Nothing abnormal was felt on rectal examination. On the next morning the patient was more comfortable. The physical signs remained the same, save that now the red area comprised a circle of about eight inches diameter, with the vulva, which was a little excoriated, at the centre. The edge of the patch was definite but was not raised. The temperature was 100° and there had been no sickness. The bowels had not been opened. Calomel and salines were ordered. Milk was taken well. Later, ten grains of compound powder of scammony were ordered. During the same night the patient suddenly collapsed and died.

At the necropsy the chest was normal save for congestion of the lungs. The abdomen contained about a pint of evil-smelling fluid just becoming turbid and a small quantity of flaky yellow lymph in the left side of the pelvis. There was general peritonitis and no localised collections of pus could be made out. The genitalia and the appendix were normal. There was congestion of the intestines but no ulceration. Peyer's patches were a little enlarged. The spleen and liver were normal. The kidneys were a little enlarged. The cortex was injected and showed fatty change. The capsule stripped readily and the stellate veins were congested. The vena cava was normal. The brain was not examined (by request). Sections were cut and examined microscopically of the spleen, the kidneys, and a Peyer's patch. The kidneys were in a state of early tubal nephritis. No organisms were seen in the sections nor in those of the spleen and Peyer's patch. Films of the pus (from the yellow flaky lymph) stained by Gram's method yielded a Gram-positive capsulated diplococcus morphologically identical with the pneumococcus. The blood in the femoral vein when cultivated gave the same organism.

A search through the records of the hospital was made in order to see what other cases of the disease had been met with and resulted in the discovery of 12 cases which are briefly summarised as follows.

CASE 5.—The patient was a male, aged 15 months. He had had cough and diarrhœa for some days. He died shortly after admission. At the necropsy broncho-pneumonia was found throughout both lungs, also propericarditis, thick lymph on the upper and lower surfaces of the right lobe of the liver, meningitis, and double otitis media. Pneumococci were found pure in films from the brain and the pericardium and in films from the peritoneum pneumococci and bacillus coli communis (necropsy 52 hours after death). In films from the lungs there were pneumococci and other organisms.

CASE 6.—This patient was a female, aged 23 months, who had been vomiting for four days. She was admitted for severe broncho-pneumonia, of which the signs were typical. The abdomen was prominent, distended, and resistant. There was constant vomiting. The patient died a few days later, the signs being unchanged. At the necropsy both the pleural cavities contained lymph, less than one ounce of fluid being present; the pericardium was normal and the liver and spleen were coated with lymph. There were general suppurative peritonitis and caries of the right petrous bone (there had been no aural discharge while in hospital). The brain was hyperæmic but there was no meningitis. In films from the ear and the peritoneum chains of strepto-diplococci, morphologically identical with the pneumococcus, were found.

CASE 7.—The patient was a male, aged five months. He had a sudden onset of screaming and fits. There was no diarrhœa or vomiting. He had flatulence and great abdominal distension. On admission there were râles at both bases; there was an impaired note at the right base. Cardiac dulness was increased; the sounds were pure. There was no marked tenderness of the abdomen and no tumour could be felt. The head was retracted and rigid. The patient died in 24 hours. At the necropsy there were small diaphragmatic empyemata at both bases, also propericarditis; the spleen was coated with lymph and there was a little turbid sero-pus in the pouch of Douglas. There was suppuration in the right middle ear, also suppurative meningitis. The pericardial pus showed pneumococci and a few staphylococci on film preparations.

CASE 8.—The patient was a male, aged 20 months. He was admitted with signs of left empyema. This was evacuated. Six days later sickness began; there was no diarrhœa. Sudden death occurred ten days after operation. At the necropsy there were some adhesions in the left pleural cavity and some lymph; the right was healthy. The pericardium was normal. In the peritoneum there were four ounces of pus and thick yellow sediment in the pouch of Douglas, lymph thickly coating the liver and the spleen; there were no adhesions between the coils of intestine. The ears were normal, also the meninges. Pneumococci were present pure in the pus from the empyema.

CASE 9.—The patient was a female, aged three years and nine months. There had been a gradual onset for 14 days. She had headache, drowsiness, and anorexia, and five days before admission she became worse, with severe pain in the abdomen. Next day she had diarrhœa and vomiting, the former for one day, and the latter had continued since. She had constipation on admission. She looked very ill, had facies abdominalis, and the knees were drawn up. There were fine rhonchi in both lungs. The heart was normal. The abdomen was very distended, there was no marked tenderness; it was very rigid, especially on the left side, and resonant all over. There were severe diarrhœa and vomiting. On the next day the patient was weaker and there was less distension. On the following day the distension practically disappeared, diarrhœa was severe, the patient was very restless, and death ensued. At the necropsy there was double empyema, three ounces of pus in all, propericarditis, general purulent peritonitis, thick lymph on the upper surface of the right lobe of the liver, the under surface of the left lobe, the upper and outer surfaces of the spleen, the under surface of the stomach, and the intestinal folds. Films of the pleural, pericardial, and peritoneal pus showed pure pneumococci.

CASE 10.—The patient was a female, aged four years and eight months. She had had whooping cough five months before; one month before she had had pain in the chest, dyspnœa, and wasting. On admission there were signs in the right lung which led to operation for empyema 14 days later. The abdomen was normal and the spleen was palpable. 15 days after admission the abdomen became slightly swollen and tender. The child did not improve and died a few days later. At the necropsy in the right pleura was an old empyema cavity; the lower lobe of the right lung showed croupous pneumonia. With regard to the left pleura there was semi-solid greenish lymph from the base to the apex. There was propericarditis (greenish pus). In the abdomen there were two ounces of turbid fluid, with flakes of lymph in places, for the most part round the liver. There was some œdema of the meninges. Cultures of the heart's blood yielded pure pneumococci.

CASE 11.—The patient was a male, aged 21 months. He had been feverish for nine days. Six days ago he vomited and had cough and delirium and cried before micturition. On admission he had cyanosis and was very ill. There were signs of fluid at the left base. Two ounces of turbid fluid were aspirated. Three days later ten ounces were withdrawn, followed by death on the next day. At the necropsy, in the left pleura there was greenish lymph and croupous pneumonia at the lower lobe of the left lung. In the right pleura there were turbid fluid and general coating of lymph. Propericarditis was present. There was recent lymph and roughening of the peritoneal covering of the spleen. The remainder of the peritoneum was normal. Films of the pericardial and left pleural fluids showed pure pneumococci.

CASE 12.—The patient was a male, aged 20 months. Ten weeks ago he had had broncho-pneumonia. Since then he had been wasting, had anæmia, and a cough. He was admitted with signs of right-sided empyema which was operated on and two and a half ounces of pus were withdrawn. 11 days later he had broncho-pneumonia at the right apex and two days later death ensued. At the necropsy he had broncho-pneumonia in the right lung, the empyema cavity draining well. There was broncho-pneumonia in the left lung. The pericardium and meninges were normal. In the abdomen there was half a pint of green oily pus, there were no adhesions or roughening of the peritoneum. The films of pus from the empyema showed pneumococci alone.

CASE 13.—The patient was a male, aged four weeks. The umbilical cord dropped off on the twelfth day; for a few days there was a slight discharge. On the eighteenth day there were vomiting and diarrhœa with green stools, and swelling of the abdomen. He had since vomited often, but the diarrhœa was less marked. On the twenty-sixth day swelling of the abdomen was more marked; the patient seemed in great pain and the urine was scanty. Discharge from the navel began again on the day of admission (the twenty-eighth). On admission the patient was found to be small and thin; there was no abdominal facies, the pulse was good, and there was no œdema. The abdomen was very distended, tense, reddish blue, and the veins were distended; there was a yellow discharge from the umbilicus. No tumour was felt; there was a fluid thrill. The umbilicus was protuberant. The whole of the right side of the abdomen was dull, save just above the pubes, and dulness extended one inch to the left of the middle line and was not moveable. The chest was normal. Under an anæsthetic five hours later the abdomen was resonant all over. At the operation a "cyst" presented in the wound covered with thickened peritoneum, which was incised; a large quantity of pus escaped. Death occurred on the next day. At the necropsy in the right pleura were blood-stained fluid and shreds of lymph; there was no pneumonia in the right lung; the diaphragm was markedly œdematous. The left pleura was normal. The intestines were matted together and pressed against the spine. There were an empty potential cavity in front, little lymph, and pus in the splenic region and between the stomach and the colon—pale yellow. The umbilical vein was normal. Films of the pus showed pneumococci only.

CASE 14.—The patient was a female, aged eight years. She had had a cough for one month, with two days of vomiting, some delirium, and pain in the left side and fever. She had been worse for a week. On admission she was thin, blue, very ill, and had rapid respirations and clubbed fingers. The left chest was obviously full of fluid. The abdomen was distended and tender. Operation was performed for empyema and a pint of pus was evacuated. Diarrhœa and vomiting occurred during the next five days; on the sixth day there were distension and tenderness of the abdomen, which increased rapidly. There was constant vomiting, the face became abdominal in expression, and death followed on the twelfth day. At the necropsy there was an old empyema in the left pleural cavity; there was no pneumonia on the left side. In the right pleura was an empyema, with three ounces of greenish pus. There were general peritonitis and coils of bowel loosely adherent, covered with recent green lymph. On the under surface of the diaphragm on the left side was a thick layer of drier lymph. Film preparations of the peritoneal fluid showed the presence of Gram-positive diplococci along with other organisms.

CASE 15.—The patient was a male aged seven weeks. For two days before admission he had been restless and irritable. The day before the abdominal wall was noticed to be red. There had been no vomiting On admission there was jaundice and the patient had a dull and earthy expression. The abdomen was prominent and œdematous in its lower half; the skin was red and glazed. There was free fluid in the abdomen. The spleen extended down to the umbilicus; a friction rub was heard over it. The liver was two fingers' breadth below the ribs The abdomen was tender. The infant vomited twice and died within 24 hours. At the necropsy the chest was found to be normal, also the ears and the brain. There were six ounces of green turbid fluid in the abdomen, and lymph in the pelvis and over the organs. The liver was large, firm, jaundiced, and light green in colour. There was recent lymph on the spleen The appendix was normal. Films and cultures from the pus yielded pure growth of pneumococci.

CASE 16.—The patient was a male, aged four and a half years. For three months he had had a puffy face. Five days before admission he had general œdema, pain in the abdomen, and constant vomiting. On admission he had cyanosis, great œdema, but no signs in the chest. The abdomen was distended and there was free fluid. On the next day there were impairment of the note at the left base and pain and tenderness in the abdomen; two days later death occurred after repeated vomiting. At the necropsy each pleural cavity contained about four ounces of thin pus. There was no pneumonia. In the abdomen there were 10 ounces of thin pus and there was lymph round the spleen. The kidneys were greatly enlarged and pale, the stellate veins were engorged, and the cortex was diminished. Films and cultures from the peritoneum gave pure growth of pneumococci.

ACHONDROPLASIA: ITS OCCURRENCE IN MAN AND IN ANIMALS.

BY CHARLES R. KEYSER, F.R.C.S. ENG., F.Z.S.,
ASSISTANT SURGEON TO THE CANCER HOSPITAL, BROMPTON, LONDON, S.W.

THE disease which in this country is usually distinguished by the name of "achondroplasia" has many other synonyms. Although this title, which was originally bestowed by Parrot, is not a perfect one it is commonly used, as it is shorter than some and more correct than others. An objection to it has been raised because it suggests that there is no growth of cartilage cells at all, and this is obviously a mistake, as there is plenty of cartilaginous activity but not in the direction of increasing the length of the limb bones. Kaufmann (1892) therefore suggested the term "chondrodystrophia fœtalis hyperplastica"; this, though more correct, is unlikely to come into general use owing to its length. Other terms, such as "fœtal rickets," "congenital rickets," and "fœtal cretinism," are now no longer employed as they suggest an entirely fallacious view of the cause of the disease.

The subjects of this condition are short and stunted in their growth but as the limb bones are chiefly affected they fall under the category of micromelic dwarfs, as distinguished from microsomic, where the growth of all the bones is arrested. Judging from the statuettes of the ancient Egyptian god Pthah, many of which can be seen in the British Museum, the disease is of very ancient origin. Some of the old Egyptian metal workers are also represented as dwarfs of this type. The figure of the god Bes (Fig. 1), although very like an achondroplasiac dwarf, is thought by some to show the appearances of a cretin. Charcot and Richer[1] have also demonstrated that several of the old masters have represented in their pictures dwarfs having the characters of the disease. Velasquez painted pygmies evidently suffering from achondroplasia in some of his paintings for the Court of Philip IV. M. Poncet and M. Leriche[2] have gone much further, however, and have suggested that achondroplasiac dwarfs represent vestiges of a race of men who lived in bygone times and have now disappeared. They regard many of the existing pygmy races as examples of atavistic return to an ancient race of dwarfs who were to be found all over the world. The Akkas and Obongos are cited as types of a "physiological, hereditary, and racial achondroplasia."

FIG. 1.

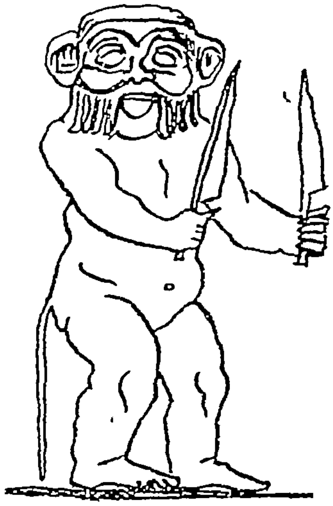

Figure of Bes.

Now, the Akkas are no doubt pygmies but are most beautifully formed and proportioned and their skeletons do not exhibit the slightest abnormality. The skull, the hands, and limb bones are all perfectly formed and do not show a trace of those changes which are pathognomonic of achondroplasia. The limb bones in particular are long and slender and not short and thick and, moreover, do not show the abnormal radio-humeral ratio. M. Poncet and M. Leriche state that these natives have a tendency to separation of the big toe from the rest of the toes and they quote this as being an approximation to the *main en trident* of achondroplasia. But in the scale of evolution the negro more nearly approaches the anthropoid apes than does the white man and the separation of the big toe is more and more marked the nearer we approach the apes and is seen in *all* negroes. Moreover, it is also seen to a certain extent in those who walk about barefooted. Although these authors give many other reasons in support of their theory they are not in the least convincing. Besides, to state that a disease (for a congenital deformity must be classed as such) is "physiological" is begging the question altogether, as a pathological state cannot be physiological.

Etiology.—The cause of achondroplasia is entirely unknown. Rickets, syphilis, and alcohol, all of which have been given as causes at various times, have not apparently anything to do with the production of the disorder. Cretinism also, is entirely distinct from it. Infants having the disease are frequently stillborn or die in early childhood, but probably many more reach maturity than was formerly thought. Thus, in the 34 cases which I have collected 18 of the subjects were over 17 years of age, seven were over 30 years, and two were over 40 years.

The disease is occasionally hereditary and it has been noticed that more than one member of a family may be affected (see Table III., cases 10 and 11, 16 and 17, 18 and 19). Porak[3] mentions the case of a woman who had the disease and gave birth to an infant similarly deformed. Boeckh[4] also published a case of a female dwarf evidently suffering from achondroplasia whose father and several other relatives had been dwarfs with similar proportions. In some cases, also, it has been found that one or both parents, although not actual examples of the disorder, are, nevertheless, of extremely small stature. Thus in Poncet and

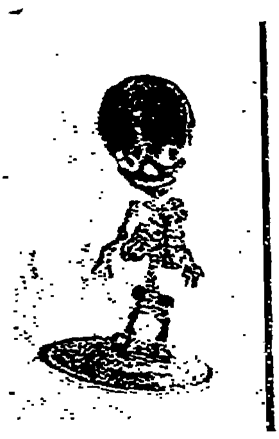
Leriche's cases (Nos. 10 and 11) both the father and mother were only just over four feet in height. In one of my cases (Case 5) the father is only four feet eight inches in height.

Pathology.—The bones of the skeleton which are formed entirely in membrane and those in cartilage which remain altogether or mainly cartilaginous till a late period of intra-uterine life are normal. Those ossified from cartilage before birth are dwarfed. Therefore the limb bones are chiefly affected, the clavicle excepted. The cause, whatever it may be, affects the infant very early, as the changes in the skeleton occur during the first few months of intra-uterine life. By the time the child is born the disease has run its course and is no longer active, so that the abnormalities seen are only the results of a malady which is passed. The skull, as a whole, is unaffected or is larger than usual; but one constant feature of the disease is premature synostosis of the basi-occipital with the basi-sphenoid. The result of this is marked depression and flattening of the bridge of the nose. The chief anatomical changes which take place have been summed up very concisely by William Turner[5] and are as follows. 1. At the junction of the epiphysis and the diaphysis the cells are abnormal as regards their size, shape, and arrangement, and the primary bony areolæ which usually lie in the axis of the bone are absent. As a result the diaphysis does not increase in length. 2. There is an ingrowth of the periosteum between the epiphysis and the diaphysis, so that the ossification of the cartilage cells in the primary areolæ is absolutely prevented. Occasionally the epiphysis and diaphysis remain ununited. The periosteum continues to form bone along the shaft, which may be unduly thick in proportion to its length and may present irregular bosses like exostoses. Sometimes the bones are soft and bend, but this is more frequently seen in the lower than in the upper extremities. (See Fig. 2.)

Symptoms.—The appearance of the patient is at once most striking and characteristic, as the marked disproportion between the length of the trunk and that of the limbs and the large size of the head are obvious to the most casual observer. The head is large, rounded, and in shape resembles that of a person suffering from hydrocephalus; the fontanelles remain open for an abnormally long period of time and are usually very large. Craniotabes is not present. The face in relation to the skull is small; there is a marked depression of the bridge of the nose due to the premature ossification of the occipital bone with the sphenoid. Dentition is normal but the palate is, as a rule, rather more arched than usual. In some cases the mouth may be kept half open and the tongue slightly protruded, but this is by no means a constant feature. In Fig. 3 the child shows this habit and the mother, whose face does not appear in the reproduction of the photograph, manifested the same peculiarity. In contra-distinction to cretinism the intelligence is exceptionally good.

FIG. 2.

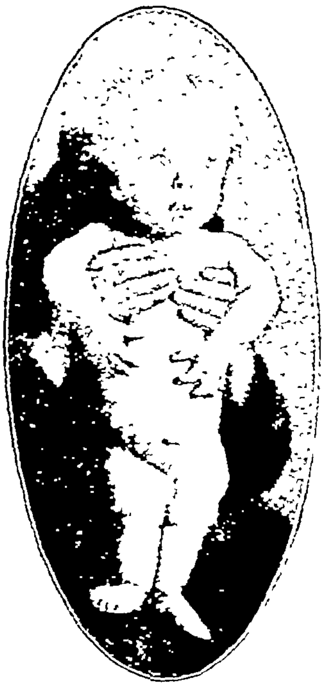


Skeleton of an achondroplasiac fœtus at term.

The trunk.—This is normal in length but the ribs are usually "beaded" anteriorly; this beading is not the same as that due to rickets. Lordosis is usually present and is due to an abnormal anterior projection of the lumbar vertebræ, as it does not disappear on placing the patient on the back and elevating the legs. Owing to the lordosis the abdomen is prominent and the buttocks project (see Fig. 4). In one of my cases, however (Case 5), lordosis was absent and a marked kyphosis, similar to that due to rickets, took its place.

The limbs—upper extremity.—The clavicle shows no abnormal change but the humerus, radius, and ulna are very short and thick and may be slightly curved; this curvature is less often seen in the upper than in the lower extremity. The elbow can seldom be extended beyond an angle of 135° and this gives the arm an appearance of being curved with the concavity inwards. Bosses of bone can occasionally be felt on the diaphyses. The epiphyses are very broad and thick; this is most marked at the lower end of the humerus.

FIG. 3.



Child, aged one year and three months (No. 5 in table), showing *main en trident*, &c.

It has been stated by many writers that the normal ratio of the length of the arm to the forearm is reversed in achondroplasia—i.e., the forearm is longer than the arm. This is so in the majority of instances but is by no means the case in all. Thus, out of 26 cases where the measurements were given the forearm was longer than the arm in only 13 instances. In four cases the arm and forearm were of the same length. As the greater number of recorded cases are those of children I thought that this "reversed ratio" might only obtain before adolescence was reached. But although the "reversed ratio" still held, yet the proportion was altered.

TABLE I.—*Showing the Proportional Length of the Forearm to the Arm in 26 Cases.*

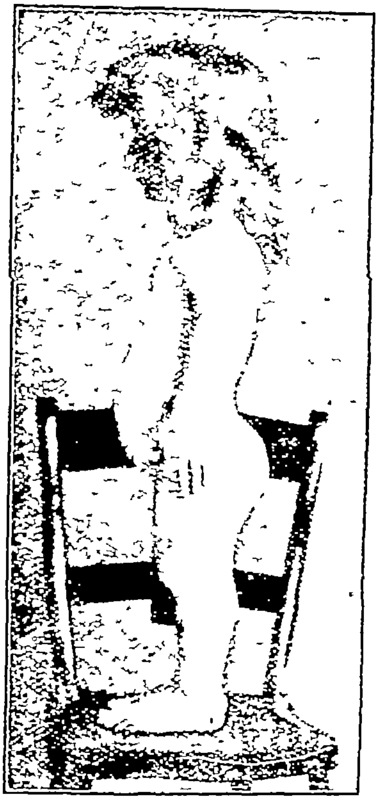
—	Under 20 years of age.	Over 20 years of age.	Total.
The forearm longer than the arm ...	8	5	13 or 50%
The forearm shorter than the arm ...	5	4	9 or 34·6%
The forearm same length as the arm	3	1	4 or 15·3%

The hands are of a peculiar shape, being broad and short, and the fingers are short and tapering. The proximal phalanges are so much broader than the terminal ones that the finger-tips cannot be approximated. There is thus a space left between the ends of the fingers, and this space is especially marked between the middle and ring fingers, so that the index and middle fingers are directed to the radial and the ring and little fingers to the ulnar side of the hand. This is the so-called *main en trident* (see Fig. 3). An abnormal range of movement is usually present in all the joints below the wrist, so that the dorsal aspects of the fingers can be made to touch the back of the forearm with ease. The thumb and little fingers can also, as a rule, be bent so as to touch the radial and ulnar borders of the forearm respectively.

---

[5] Practitioner, vol. lxiii., 1899.

FIG. 4.



Child, aged six years (No 6 in table), showing lordosis, &c.

Lower extremity.—The changes are very similar to those observed in the upper extremity, the bones being very short and thick and frequently present bosses, especially in the neighbourhood of the knee-joint. As in the upper extremity, it has been stated that the leg is longer than the thigh, but on examining the figures in 23 cases I find that the reverse of this is the case.

TABLE II.—*Showing the Length of the Leg and the Thigh in 23 cases.*

—	Under 20 years of age.	Over 20 years of age	Total.
The leg shorter than the thigh ..	9	5	14 or 60·9%
The leg longer than the thigh ...	5	4	9 or 39 1%

The fibula, however, is peculiar in that in nearly all cases the upper end enters into the formation of the knee-joint. On the anterior aspect of the knee deep annular folds of the skin can frequently be seen, as if the integuments were too long for the bones. The tarsus, metatarsus, and phalanges are normal. The pelvis is small and narrow and in the event of a female achondroplasiac dwarf becoming pregnant there may be considerable difficulty and danger in parturition. The muscles are usually well developed and as the limb bones are very short the leverage obtained is enormous, so that all sorts of acrobatic feats can be performed with ease. Thus, for instance, one of my subjects (Case 6) could touch the floor with his forehead with ease whilst walking or running. He could also sit down and rise up again without bending the knees and could turn back somersaults without any difficulty whatever.

Diagnosis.—The conditions for which achondroplasia is liable to be mistaken are rickets and cretinism. But errors in diagnosis ought seldom, if ever, to be made, as the diseases present quite different symptoms.

Rickets.—In the first place, the signs of achondroplasia are present at birth, whereas those of rickets seldom appear before the end of the first year. A certain number of cases of so-called congenital rickets have been recorded, but it is exceedingly doubtful if the disease really exists. Moreover, there is no disproportion in the length of the body to the limbs in rickets, the curvatures of the bones are usually distinct, and the characteristic signs of achondroplasia—viz., the shape of the fingers, the short and broad limb bones, the depressed nose, &c —are absent.

Cretinism.—Here the disease is congenital, but although the growth of the child is stunted the limbs are not unduly shortened in relation to the length of the body. The half-open mouth allows the large size of the tongue to be seen, the hair is coarse and scanty, and the skin is rough; supraclavicular fatty pads are usually present and the absence of, or much diminished size of, the thyroid gland may be made out. Again, the signs characteristic of achondroplasia are absent. If, in spite of these differences, the diagnosis is still uncertain the effects of treatment will soon clear up any difficulty, as both rickets and cretinism are readily amenable to treatment, whilst achondroplasia is unaffected by any treatment, either medicinal or dietetic.

THE OCCURRENCE OF ACHONDROPLASIA IN ANIMALS.

Several writers (Ballantyne,[6] Poncet and Leriche and others) have stated that achondroplasia occurs in animals and have suggested that dachshunds, basset hounds, Ancon sheep, &c , are examples of the disease. Evidence for and against the theory is somewhat difficult to procure but so far as I can make out there is no proof whatever that the disease does occur in animals. The various animals suggested will now be dealt with seriatim.

Dogs—Dachshunds.—The striking appearance of these animals, with their short and crooked legs and long body, has no doubt been the reason for supposing that achondroplasia is the cause. The following extracts, however, throw some light on the matter:—

> Though the origin of the dog generally is lost in obscurity, yet the dachshund can claim a very long pedigree, for a dog resembling it is found on the monument of Thothmes III , who reigned over Egypt more than 2000 years B C and at whose Court the inscriptions state he was a favourite, and a breed of similar appearance has been discovered by Dr *Haughton on early Assyrian sculptures No doubt research* would bring to light other notices of the same kind, but these show that the abnormal shape of the forelegs is not due to disease, as has been supposed by some who have not studied these dogs. ...... This peculiarity (i e., the short limbs, &c.) is more commonly found than is generally imagined Beside the basset, both rough and smooth, and the dachshund of France, it is apparent in an Indian breed, in the Swedish beagle, in the spaniel of Hungary and Transylvania, and almost certainly *in the old English bloodhound, though* judges, setting Shakespeare at nought, are trying to get rid of it as a deformity—Lovell.[7]

And again, Darwin[8] says:—

> *On Egyptian* monuments *from* the fourth to the twelfth dynasties (i e., from about 3400 B C. to 2100 B C.) several varieties of the dog are represented . There is also a turnspit with short and crooked legs, closely resembling the existing variety, *but this* kind of monstrosity is so common with various animals, as with the Ancon sheep, and even according to Rengger, with jaguars in Paraguay, that it would be rash to look at the monumental animal as the parent *of* all of our turnspits.

Now, *it is* inconceivable *that, even supposing* that an ancient Egyptian dachshund was afflicted with achondroplasia, *every separate individual born during* the last 3000 years should also be affected with the disease. Such a *condition* of things is absolutely unknown in pathology. It is much more likely that the shape of the dachshund arose *suddenly* as a variation and that it has been preserved by selection, either natural or artificial, through man.

> Some *of the peculiarities* characteristic of the several breeds of the dog have probably arisen suddenly and, though strictly inherited, may be called monstrosities, *for* instance, the shape of the legs and body in the turnspit of Europe and India. . . A peculiarity suddenly arising, and therefore, in one sense, deserving to be called a monstrosity, may however be increased and fixed by man's selection.—Darwin.[9]

In Cases 10 and 11, 16 and 17, and 18 and 19 respectively the subjects were brothers and sisters. * The same patient at different ages.

Remarks.—CASE 5.—The *bridge of the* nose is markedly depressed. The hands with arms outstretched reach only *to* the umbilicus. *Main en trident.* No lordosis. Kyphosis present. Father only 4 feet 8 inches in height. Mother normal. CASE 6.—Marked depression of the bridge of the nose. *Main en trident.* Marked lordosis. No annular folds of skin about the knees. Very intelligent. Has grown two inches in one year. Parents normal. CASE 10.—Grandfather 4 feet 5 inches, also father. Mother 4 feet 7 inches. The bridge of the nose is slightly depressed. The hands are not typical. CASE 11.—*Main en trident* (slight). Very intelligent. CASE 15.—*Main en trident.* CASE 34.—Very intelligent. *Main en trident.* Both parents normal.

Moreover, on examining the skeleton of a dachshund there is not the least suspicion of any osseous disease. The fore-arms and legs are not longer than the arms and thighs, the epiphyses are normal, and the skull is not enlarged. The fibula does not enter into the formation of the knee-joint and the nasal bones are not depressed. If achondroplasia is diagnosed solely on account of the shortness of the legs as compared to the body, then basset hounds, Skye terriers, Aberdeen terriers, Yorkshire terriers, &c., must all be examples of the disease.

Cattle, &c.—Bull-dog calf.—This animal, which is always stillborn, is occasionally seen as the offspring of the Dexter Kerry cow. It is very small, being of about the size of a fox terrier, and has very short limbs as compared to the length of the body. It has received its name, however, from the extraordinary appearance of its face; this somewhat resembles a bull-dog owing to the shortness of the upper lip and jaw, the flattening of the nose, the wide nostrils, the projection of the lower jaw and lip, and the exposure of the gums. There is no reason for supposing that this condition is due to achondroplasia and it must be regarded simply as a monstrosity or "sport." This appearance of "bull-dog face" is not at all uncommon amongst animals, for besides the well-known examples, such as the bull-dog, pug, King Charles and Blenheim spaniels, it is mentioned by Darwin as occurring in two small herds of cattle which he saw on the north bank of the Plata river. They go by the name of Niata or Natas. The same authority quotes Professor Wyman of Cambridge, U.S.A., who observed the same thing in codfish. Mr. Boulenger, vice-president of the Zoological Society of London, informs me that a similar condition exists in carp, salmon, &c., and also in reptiles. E. Ray Lankester,[10] in speaking about elephants, says:—

> If you look at an elephant's skull and compare it with that of a dog or pig, you will be struck by the abrupt way in which the bones of the

---

[10] Extinct Animals, 1905.

face are set. The face is almost straight so far as the bony parts are concerned—both the upper and lower jaw are quite short. There is, in fact, no "snout" indicated in the bony skull. This extreme shortening or pushing in (as it were) of the face is similar to what occurs in bull-dogs and pugs as compared with ordinary long-snouted dogs ...... only in the elephant it is carried further than in any dog. We may call this shortening of the face "bull-dogging." This "bull-dogging" of the skull occurs in a South American race of cattle called the Neatta breed. It seems that the ancestral elephants must have had a long face and bony snout like other animals but that their descendants have gradually become "bull dogged." The mastodon's skull shows far more of a projecting bony face or snout than does that of the elephant, and this would lead us to suppose that the mastodons are more primitive—that is to say, more like the ancient ancestors of elephants than are the true elephants. An interesting fact in this connexion is that the young, new-born elephant has a more "snouty" skull than the grown-up elephant. It is often the case that very young animals show features in which they resemble their ancestors which disappear as the young creatures grow to full size.

We may conclude then from these statements, made by eminent authorities, that there is no reason whatever to suppose that achondroplasia exists in animals.

TUBERCULOUS DISEASE OF THE SEMINAL TRACT.[1]

BY K. E. LEVESON-GOWER GUNN, M.D. DUB., F.R.C.S. IREL.,
ASSISTANT SURGEON TO THE ADELAIDE HOSPITAL, DUBLIN.

THERE are two classes of disease that must always be of interest to us, those that are very rare, and for this reason interesting, and those that are very common, for on our power of curing common ailments depends largely our measure of professional success. It is to a very common disease—namely, tuberculosis—that I wish to draw your attention.

The genito-urinary tract is often attacked by tuberculous disease. In some parts of this system the diagnosis may be beset with considerable difficulty; in that portion of the system, the testicle, the cord, the seminal vesicles, and the prostate, to which I wish to call your attention, the diagnosis leaves as a rule no room for doubt. When the question of treatment arises there seems to be, on the other hand, considerable difficulty in selecting the best course to pursue; for this reason I hope that this paper, since it deals more particularly with the treatment of tuberculosis of the seminal tract, may prove of interest to you.

Tuberculous disease may occur primarily in the kidney, the bladder, the prostate, the seminal vesicles, or the testicle, or it may occur as a secondary deposit in any of these organs. The testicle is most commonly affected of all these, by testicle I mean both testis and epididymis, for the latter is more often attacked than the former. There is an interesting difference between the primary and secondary infection of the epididymis by tubercle. In the primary the disease is deposited in the tubules and from its commencement is in connexion with the lumen of the vas; in the secondary the infection more commonly occurs in the connective tissue outside the tubules, and it may be months before the bacilli gain entrance to the vas. This has an important bearing on the extension of the disease from a tuberculous epididymis.

In what direction does this disease spread from the epididymis? Into the body of the testicle itself, where inflammatory changes or the actions of toxins, or perhaps both causes, early in the disease render the testicle functionless. The flow of seminal fluid along the vas is very slow except during ejaculation, when the powerful muscular walls of the vas contract strongly. The tubercle bacilli are carried along in this sluggish stream and have many opportunities of infecting the walls of the vas; they finally reach the seminal vesicles, where they are stored for a time until finally discharged into the urethra. The vas may be infected the whole way along. In early cases of its infection this commonly takes place at either end—that is, within an inch or two of the epididymis or near its termination in the seminal vesicle. The cord between these two points may be quite normal and so lead one to suppose that as the cord is healthy above a tuberculous testicle therefore the disease has not extended up along the vas deferens.

CASE 1.—In February, 1905, I saw a young man who had had one testicle removed for tuberculous mischief about two years before. The second testicle now had a similar deposit; the cord felt quite normal and we hoped to be able to curette away the disease and to save the testicle if there was no sign of infection spreading up to the seminal vesicles. Even after the cord was exposed with its veins the vas felt normal but the testicle was found too far involved to save it and it was in consequence removed, the vas being separated from the rest of the cord at the same time. It then became apparent that the vas was not healthy; two minute nodules were situated in its wall about an inch above the testicle. As much as possible of the cord was removed and inside the abdomen two more small nodules were found on the vas. Rectal examination showed no sign of infection of the prostate or seminal vesicles, but I fear that this may occur later.

The disease often attacks the second testicle and from there it may extend backwards along the cord to the seminal vesicle on the same side, or the reverse may occur, the second vesicle being infected from the first vesicle or the prostate and from this the tubercle spreading to the testicle against the direction of the seminal flow. That infection can go in this direction we all know from cases that are not uncommon of sepsis spreading from the posterior urethra to the epididymis.

The age at which tubercle shows itself in the epididymis is about from 16 to 24 years, seldom after this, though deposits sometimes occur in infants. Injury is the most commonly assigned cause, where any cause at all is given. I think that a form of what I might almost call chronic injury is not without importance—I refer to masturbation. This is an unsavoury subject to discuss and for this reason is ignored to a greater extent by most surgeons than it deserves to be. So often in taking the histories of severe cases of genito-urinary tuberculosis have I learned that the patient was a masturbator and continued this practice after the first appearance of the disease that I feel confident that masturbation has a direct bearing both on the causation and the spread of tuberculosis of the genital tract. Where only one testicle is affected, as a rule the surgeon will not hesitate to remove the disease; in all probability to do this completely will necessitate the removal of the testicle. This loss is not a serious one from the patient's point of view and the operation is often attended with the most satisfactory results. Sometimes this is not so, and later the disease appears in the second testicle or when the patient first presents himself both the testes may be already infected. In these circumstances general anti-tuberculous treatment may be used, a partial operation may be done—i.e., the disease scraped away as completely as possible—or a complete operation may be done and both testicles removed.

Castration is a very serious operation from the patient's point of view and unless his surgeon can promise him almost certain success as the result of the operation he will hardly submit to it, even though the testicles themselves are functionless. I have already called your attention to the fact that early in the course of the disease, be it in testis or epididymis, the function of the testicle is lost; it is in these circumstances useless to the patient and a source of danger to him. If the disease has extended to the prostate, seminal vesicles, or bladder there is not much use in removing the testes and hoping that this may check the disease, for such hopes are not likely to be realised. This procedure has been often recommended but I do not think that it ever stops the advance of the disease, indeed, I believe that it has quite the opposite effect, that in reality it lessens the resisting power of the prostate and vesicles to withstand the advances of the tubercle, for the removal of the testes leads to a gradual atrophy of these organs, and with this atrophy there will in all probability be a diminished power of resistance to disease.

Can the extent to which the disease has spread be definitely made out? In most cases it can; if the urine is clear, if the bladder holds from 12 to 14 ounces without pain, and if there is no frequency of micturition, in all probability the bladder is not infected. Still infection of the bladder sometimes occurs as submucous tubercles which may give rise to no symptoms; they can be readily seen through a cystoscope. It is well in all such suspected cases to examine the bladder by this means.

Infection of the seminal vesicles and prostate may give rise to similar symptoms to those of bladder infection, and here, again, it is advisable to make a cystoscopic examination. On the other hand, I have seen several cases of infection of both prostate and vesicles in which there were no symptoms beyond a slight feeling of weight in the perineum, yet on rectal examination extensive disease of these organs could be easily made out. Nodules in the prostate can be readily felt by the examining finger in the rectum, but the vesicles are harder to reach; fully distending the bladder with from 20 to 30 ounces of an unirritating antiseptic lotion, and then placing the patient in the knee-chest position will be found of assistance in carrying out this examination.

---

[1] A paper read before the Surgical Section of the Royal Academy of Medicine in Ireland on Dec. 1st, 1905.

I next wish to draw your attention to the course which this disease takes when the entire seminal tract is involved. I can best do this by describing three typical cases which have lately passed through my hands.

CASE 2.—In August, 1905, I saw a man, aged 25 years. He told me that five years before the left testicle became swollen and discharged pus through the scrotum for several months and then was pronounced well; six months later the other testicle became enlarged, broke, discharged for six weeks, and then healed. For a year all went well, then an abscess appeared in his right groin, and this abscess had never completely healed. Four months previously the bladder became involved, there had been increasing distress since then. His present condition was as follows. His urine contained a quantity of pus, blood, and tubercle bacilli; he passed urine every ten minutes day and night; pain was always present and often very severe. There were tuberculous nodules in each epididymis, in the prostate, and in both seminal vesicles; the cords felt normal. The bladder was highly inflamed; tuberculous ulceration had occurred in several places; the mouths of both ureters were patulous. The disease will almost certainly extend up to the kidneys if it has not already done so.

CASE 3.—A strong-looking man, aged 28 years, was admitted to the Adelaide Hospital under my care in March, 1905. From the age of 16 years he had been a confirmed masturbator. At 20 years he developed a small nodule in his left testicle; this was treated for some months with applications and finally ceased to trouble him. Three years later a similar nodule appeared in his right testis. After a time this broke and finally had to be scraped out. For two years after this he kept well, then the testis broke out again and symptoms of irritation at the neck of the bladder began to show themselves and pus appeared in the urine. A month before admission he was attacked by pain in the region of his left kidney; this pain had never since left him. He had great pain on passing urine, this he had to do every few minutes during the day and about every half hour through the night. The urine was foul and contained a considerable amount of pus. Tubercle bacilli were present. There were tuberculous deposits in both epididymi, in the right vas, and in both seminal vesicles; the lower end of the left ureter could be felt much enlarged; the left kidney was swollen and tender. The walls of the bladder were inflamed and in places ulcerated. The mouth of the left ureter was wide open, from it pus was coming. The left kidney and ureter are infected in this case

CASE 4.—A soldier, aged 26 years, was admitted to hospital under my care in January, 1905. He was a confirmed masturbator until about the age of 20 years. At the age of 21 years, while serving in Egypt, a small tuberculous nodule developed in his right testicle; it gave him no pain or inconvenience and was not treated. Two years later, while serving in South Africa, the other testicle became affected. He was sent into hospital where the testis was removed. In six weeks he was back on duty again, his health during the whole time being excellent. Two years later bladder symptoms began to come on; pus appeared in the urine, pain became severe, and finally he was invalided from the service. When I saw him his condition was pitiable. The right testicle, vas, both seminal vesicles, and prostate were infected; there was extensive ulceration in the bladder. From the right kidney a quantity of pus was coming; the kidney itself was much enlarged and tender; the left kidney was also painful and the urine coming from it contained pus. The urine was voided every few minutes; it contained numbers of bacteria and among them tubercle bacilli. To try to relieve the intense pain in the right kidney I drained it from the loin. It was a mere bag of foul pus; this drainage gave temporary relief. He was moved to the Rest for the Dying and died there some two months later.

These three cases have many points in common. I could find no sign of tuberculous disease outside the genito-urinary tract; in each the deposit in the testicle was, I think, primary. This was followed by the infection of the vesicles, prostate, and remaining testicle at varying intervals; from this the disease spread to the bladder; in Case 3 it had reached one kidney; in Case 4 it had destroyed the kidneys and finally put an end to years of suffering. I fear that the same fate is in store for Cases 2 and 3; treatment may delay, but will hardly prevent, a similar termination. The disease occurred in otherwise healthy young men who all had surgical advice and the means to carry out the treatment ordered. In the worst case the disease developed while the patient was in Egypt and South Africa, both climates which should have helped to stay its progress. These three patients would have submitted to any operation, no matter what mutilation it might entail, if it would relieve their pain, even if it did not cure, but beyond draining the kidney in the one case I did not see that any operative interference was justified.

I have given these cases in some detail for they are, I think, typical of their class and because they have left a vivid picture on my mind of the course and termination of this disease. Of earlier cases occurring during the past five years, in which both testicles and prostate or seminal vesicles were infected, some I have been unable to trace, but in all those that I have been able to follow the disease has progressed from the seminal tract to the bladder and from there has infected some vital organ, eventually causing death. I may have been unfortunate in the cases which have come under my notice. They have compelled me to believe that the ordinary methods of treating this form of the disease, such as open air, dry climate, forced feeding, &c., combined with partial operations, such as scraping away the tuberculous deposit from the testicle, are of little avail in checking its course and offer small hope of cure to the patient.

CASE 5.—In January, 1905, a young man, aged 22 years, was admitted under my care at the Adelaide Hospital. From the age of 15 years he had constantly masturbated; he attributed all his trouble to this vice. Three years before his left testicle became swollen and painful. This swelling passed off, leaving a small hard nodule in his epididymis; this nodule gave him no further trouble. Three months before admission his right testicle began to swell, broke, and pus came away. On admission there was a hard tuberculous node in his left epididymis; the vas above this felt normal. On the right side the whole testicle and epididymis were tuberculous. A sinus led to the former from which pus was coming. The vas above felt as thick as a lead pencil right up to the inguinal canal. With a finger in the rectum the vas on the same side could be felt still thickened as it passed into the prostate. The vesicles and prostate itself felt normal. The urine was normal. Cystoscopic examination of the bladder showed it to be quite healthy. I advised the removal of the right testicle and, if possible, the whole of the vas. This I tried to do by following up the vas into the inguinal canal, the floor of which I opened, dividing the deep epigastric artery. I could not get the entire vas away through this anterior incision and left behind about an inch of it. I left in a small drain but nothing came away and the wound healed in ten days.

On his discharge from hospital the patient was given orders to report himself to me once a month in case of further infection taking place. He did not come for three months; one end of the wound had opened and was discharging tuberculous pus, evidently from the remains of the diseased vas, the remaining testicle and cord showed signs of fresh infection, and tuberculous nodules could be felt in the prostate and both seminal vesicles; there was, in fact, active disease of the whole seminal tract. The urine remained normal, the bladder was healthy, but I could see the swollen right vesicle bulging up into the base of the bladder. I felt that the only treatment which offered a reasonable hope of success was the removal of the whole of the disease; the remaining testicle was useless and should be removed; with it should come both cords, vesicles, and prostate if this could be done without great risk to the patient.

There are three different routes by which the vesicles may be reached—Zuckerkandl's by a perineal incision; Kraske's by removing a portion of the sacrum, pulling the rectum to one side, and so exposing the base of the bladder; and Young's, who by a large T-shaped incision through the lower part of the abdominal wall dividing both recti muscles, gets face are set. The face is almost straight so far as the bony parts are concerned—both the upper and lower jaw are quite short. There is, in fact, no "snout" indicated in the bony skull. This extreme shortening or pushing in (as it were) of the face is similar to what occurs in bull-dogs and pugs as compared with ordinary long-snouted dogs ...... only in the elephant it is carried further than in any dog. We may call this shortening of the face "bull-dogging." This "bull-dogging" of the skull occurs in a South American race of cattle called the Neatta breed. It seems that the ancestral elephants must have had a long face and bony snout like other animals but that their descendants have gradually become "bull dogged." The mastodon's skull shows far more of a projecting bony face or snout than does that of the elephant, and this would lead us to suppose that the mastodons are more primitive—that is to say, more like the ancient ancestors of elephants than are the true elephants. An interesting fact in this connexion is that the young, new-born elephant has a more "snouty" skull than the grown-up elephant. It is often the case that very young animals show features in which they resemble their ancestors which disappear as the young creatures grow to full size.

We may conclude then from these statements, made by eminent authorities, that there is no reason whatever to suppose that achondroplasia exists in animals.

TUBERCULOUS DISEASE OF THE SEMINAL TRACT.[1]

BY K. E. LEVESON-GOWER GUNN, M.D. DUB., F.R.C.S. IREL.,

ASSISTANT SURGEON TO THE ADELAIDE HOSPITAL, DUBLIN.

THERE are two classes of disease that must always be of interest to us, those that are very rare, and for this reason interesting, and those that are very common, for on our power of curing common ailments depends largely our measure of professional success. It is to a very common disease—namely, tuberculosis—that I wish to draw your attention.

The genito-urinary tract is often attacked by tuberculous disease. In some parts of this system the diagnosis may be beset with considerable difficulty; in that portion of the system, the testicle, the cord, the seminal vesicles, and the prostate, to which I wish to call your attention, the diagnosis leaves as a rule no room for doubt. When the question of treatment arises there seems to be, on the other hand, considerable difficulty in selecting the best course to pursue; for this reason I hope that this paper, since it deals more particularly with the treatment of tuberculosis of the seminal tract, may prove of interest to you.

Tuberculous disease may occur primarily in the kidney, the bladder, the prostate, the seminal vesicles, or the testicle, or it may occur as a secondary deposit in any of these organs. The testicle is most commonly affected of all these, by testicle I mean both testis and epididymis, for the latter is more often attacked than the former. There is an interesting difference between the primary and secondary infection of the epididymis by tubercle. In the primary the disease is deposited in the tubules and from its commencement is in connexion with the lumen of the vas; in the secondary the infection more commonly occurs in the connective tissue outside the tubules, and it may be months before the bacilli gain entrance to the vas. This has an important bearing on the extension of the disease from a tuberculous epididymis.

In what direction does this disease spread from the epididymis? Into the body of the testicle itself, where inflammatory changes or the actions of toxins, or perhaps both causes, early in the disease render the testicle functionless. The flow of seminal fluid along the vas is very slow except during ejaculation, when the powerful muscular walls of the vas contract strongly. The tubercle bacilli are carried along in this sluggish stream and have many opportunities of infecting the walls of the vas; they finally reach the seminal vesicles, where they are stored for a time until finally discharged into the urethra. The vas may be infected the whole way along. In early cases of its infection this commonly takes place at either end—that is, within an inch or two of the epididymis or near its termination in the seminal vesicle. The cord between these two points may be quite normal and so lead one to suppose that as the cord is healthy above a tuberculous testicle therefore the disease has not extended up along the vas deferens.

CASE 1.—In February, 1905, I saw a young man who had had one testicle removed for tuberculous mischief about two years before. The second testicle now had a similar deposit; the cord felt quite normal and we hoped to be able to curette away the disease and to save the testicle if there was no sign of infection spreading up to the seminal vesicles. Even after the cord was exposed with its veins the vas felt normal but the testicle was found too far involved to save it and it was in consequence removed, the vas being separated from the rest of the cord at the same time. It then became apparent that the vas was not healthy; two minute nodules were situated in its wall about an inch above the testicle. As much as possible of the cord was removed and inside the abdomen two more small nodules were found on the vas. Rectal examination showed no sign of infection of the prostate or seminal vesicles, but I fear that this may occur later.

The disease often attacks the second testicle and from there it may extend backwards along the cord to the seminal vesicle on the same side, or the reverse may occur, the second vesicle being infected from the first vesicle or the prostate and from this the tubercle spreading to the testicle against the direction of the seminal flow. That infection can go in this direction we all know from cases that are not uncommon of sepsis spreading from the posterior urethra to the epididymis.

The age at which tubercle shows itself in the epididymis is about from 16 to 24 years, seldom after this, though deposits sometimes occur in infants. Injury is the most commonly assigned cause, where any cause at all is given. I think that a form of what I might almost call chronic injury is not without importance—I refer to masturbation. This is an unsavoury subject to discuss and for this reason is ignored to a greater extent by most surgeons than it deserves to be. So often in taking the histories of severe cases of genito-urinary tuberculosis have I learned that the patient was a masturbator and continued this practice after the first appearance of the disease that I feel confident that masturbation has a direct bearing both on the causation and the spread of tuberculosis of the genital tract. Where only one testicle is affected, as a rule the surgeon will not hesitate to remove the disease; in all probability to do this completely will necessitate the removal of the testicle. This loss is not a serious one from the patient's point of view and the operation is often attended with the most satisfactory results. Sometimes this is not so, and later the disease appears in the second testicle or when the patient first presents himself both the testes may be already infected. In these circumstances general anti-tuberculous treatment may be used, a partial operation may be done—i.e., the disease scraped away as completely as possible—or a complete operation may be done and both testicles removed.

Castration is a very serious operation from the patient's point of view and unless his surgeon can promise him almost certain success as the result of the operation he will hardly submit to it, even though the testicles themselves are functionless. I have already called your attention to the fact that early in the course of the disease, be it in testis or epididymis, the function of the testicle is lost; it is in these circumstances useless to the patient and a source of danger to him. If the disease has extended to the prostate, seminal vesicles, or bladder there is not much use in removing the testes and hoping that this may check the disease, for such hopes are not likely to be realised. This procedure has been often recommended but I do not think that it ever stops the advance of the disease, indeed, I believe that it has quite the opposite effect, that in reality it lessens the resisting power of the prostate and vesicles to withstand the advances of the tubercle, for the removal of the testes leads to a gradual atrophy of these organs, and with this atrophy there will in all probability be a diminished power of resistance to disease.

Can the extent to which the disease has spread be definitely made out? In most cases it can; if the urine is clear, if the bladder holds from 12 to 14 ounces without pain, and if there is no frequency of micturition, in all probability the bladder is not infected. Still infection of the bladder sometimes occurs as submucous tubercles which may give rise to no symptoms; they can be readily seen through a cystoscope. It is well in all such suspected cases to examine the bladder by this means.

Infection of the seminal vesicles and prostate may give rise to similar symptoms to those of bladder infection, and here, again, it is advisable to make a cystoscopic examination. On the other hand, I have seen several cases of infection of both prostate and vesicles in which there were no symptoms beyond a slight feeling of weight in the perineum, yet on rectal examination extensive disease of these organs could be easily made out. Nodules in the prostate can be readily felt by the examining finger in the rectum, but the vesicles are harder to reach; fully distending the bladder with from 20 to 30 ounces of an unirritating antiseptic lotion, and then placing the patient in the knee-chest position will be found of assistance in carrying out this examination.

---

[1] A paper read before the Surgical Section of the Royal Academy of Medicine in Ireland on Dec. 1st, 1905.

I next wish to draw your attention to the course which this disease takes when the entire seminal tract is involved. I can best do this by describing three typical cases which have lately passed through my hands.

CASE 2.—In August, 1905, I saw a man, aged 25 years. He told me that five years before the left testicle became swollen and discharged pus through the scrotum for several months and then was pronounced well; six months later the other testicle became enlarged, broke, discharged for six weeks, and then healed. For a year all went well, then an abscess appeared in his right groin, and this abscess had never completely healed. Four months previously the bladder became involved: there had been increasing distress since then. His present condition was as follows. His urine contained a quantity of pus, blood, and tubercle bacilli; he passed urine every ten minutes day and night; pain was always present and often very severe. There were tuberculous nodules in each epididymis, in the prostate, and in both seminal vesicles; the cords felt normal. The bladder was highly inflamed; tuberculous ulceration had occurred in several places; the mouths of both ureters were patulous. The disease will almost certainly extend up to the kidneys if it has not already done so.

CASE 3.—A strong-looking man, aged 28 years, was admitted to the Adelaide Hospital under my care in March, 1905. From the age of 16 years he had been a confirmed masturbator. At 20 years he developed a small nodule in his left testicle; this was treated for some months with applications and finally ceased to trouble him. Three years later a similar nodule appeared in his right testis. After a time this broke and finally had to be scraped out. For two years after this he kept well, then the testis broke out again and symptoms of irritation at the neck of the bladder began to show themselves and pus appeared in the urine. A month before admission he was attacked by pain in the region of his left kidney; this pain had never since left him. He had great pain on passing urine; this he had to do every few minutes during the day and about every half hour through the night. The urine was foul and contained a considerable amount of pus. Tubercle bacilli were present. There were tuberculous deposits in both epididymi, in the right vas, and in both seminal vesicles; the lower end of the left ureter could be felt much enlarged; the left kidney was swollen and tender. The walls of the bladder were inflamed and in places ulcerated. The mouth of the left ureter was wide open; from it pus was coming. The left kidney and ureter are infected in this case.

CASE 4.—A soldier, aged 26 years, was admitted to hospital under my care in January, 1905. He was a confirmed masturbator until about the age of 20 years. At the age of 21 years, while serving in Egypt, a small tuberculous nodule developed in his right testicle; it gave him no pain or inconvenience and was not treated. Two years later, while serving in South Africa, the other testicle became affected. He was sent into hospital where the testis was removed. In six weeks he was back on duty again, his health during the whole time being excellent. Two years later bladder symptoms began to come on; pus appeared in the urine, pain became severe, and finally he was invalided from the service. When I saw him his condition was pitiable. The right testicle, vas, both seminal vesicles, and prostate were infected; there was extensive ulceration in the bladder. From the right kidney a quantity of pus was coming; the kidney itself was much enlarged and tender; the left kidney was also painful and the urine coming from it contained pus. The urine was voided every few minutes; it contained numbers of bacteria and among them tubercle bacilli. To try to relieve the intense pain in the right kidney I drained it from the loin. It was a mere bag of foul pus; this drainage gave temporary relief. He was moved to the Rest for the Dying and died there some two months later.

These three cases have many points in common. I could find no sign of tuberculous disease outside the genito-urinary tract; in each the deposit in the testicle was, I think, primary. This was followed by the infection of the vesicles, prostate, and remaining testicle at varying intervals; from this the disease spread to the bladder; in Case 3 it had reached one kidney; in Case 4 it had destroyed the kidneys and finally put an end to years of suffering. I fear that the same fate is in store for Cases 2 and 3; treatment may delay, but will hardly prevent, a similar termination. The disease occurred in otherwise healthy young men who all had surgical advice and the means to carry out the treatment ordered. In the worst case the disease developed while the patient was in Egypt and South Africa, both climates which should have helped to stay its progress. These three patients would have submitted to any operation, no matter what mutilation it might entail, if it would relieve their pain, even if it did not cure, but beyond draining the kidney in the one case I did not see that any operative interference was justified.

I have given these cases in some detail for they are, I think, typical of their class and because they have left a vivid picture on my mind of the course and termination of this disease. Of earlier cases occurring during the past five years, in which both testicles and prostate or seminal vesicles were infected, some I have been unable to trace but in all those that I have been able to follow the disease has progressed from the seminal tract to the bladder and from there has infected some vital organ, eventually causing death. I may have been unfortunate in the cases which have come under my notice. They have compelled me to believe that the ordinary methods of treating this form of the disease, such as open air, dry climate, forced feeding, &c., combined with partial operations, such as scraping away the tuberculous deposit from the testicle, are of little avail in checking its course and offer small hope of cure to the patient.

CASE 5.—In January, 1905, a young man, aged 22 years, was admitted under my care at the Adelaide Hospital. From the age of 15 years he had constantly masturbated; he attributed all his trouble to this vice. Three years before his left testicle became swollen and painful. This swelling passed off, leaving a small hard nodule in his epididymis; this nodule gave him no further trouble. Three months before admission his right testicle began to swell, broke, and pus came away. On admission there was a hard tuberculous node in his left epididymis; the vas above this felt normal. On the right side the whole testicle and epididymis were tuberculous. A sinus led to the former from which pus was coming. The vas above felt as thick as a lead pencil right up to the inguinal canal. With a finger in the rectum the vas on the same side could be felt still thickened as it passed into the prostate. The vesicles and prostate itself felt normal. The urine was normal. Cystoscopic examination of the bladder showed it to be quite healthy. I advised the removal of the right testicle and, if possible, the whole of the vas. This I tried to do by following up the vas into the inguinal canal, the floor of which I opened, dividing the deep epigastric artery. I could not get the entire vas away through this anterior incision and left behind about an inch of it. I left in a small drain but nothing came away and the wound healed in ten days.

On his discharge from hospital the patient was given orders to report himself to me once a month in case of further infection taking place. He did not come for three months; one end of the wound had opened and was discharging tuberculous pus, evidently from the remains of the diseased vas, the remaining testicle and cord showed signs of fresh infection, and tuberculous nodules could be felt in the prostate and both seminal vesicles; there was, in fact, active disease of the whole seminal tract. The urine remained normal, the bladder was healthy, but I could see the swollen right vesicle bulging up into the base of the bladder. I felt that the only treatment which offered a reasonable hope of success was the removal of the whole of the disease; the remaining testicle was useless and should be removed; with it should come both cords, vesicles, and prostate if this could be done without great risk to the patient.

There are three different routes by which the vesicles may be reached—Zuckerkandl's by a perineal incision; Kraske's by removing a portion of the sacrum, pulling the rectum to one side, and so exposing the base of the bladder; and Young's, who by a large T-shaped incision through the lower part of the abdominal wall dividing both recti muscles, gets at the bladder in this way. Of these three the first is the simplest and much the least severe operation. I tried this operation several times on the cadaver but found it exceedingly difficult to reach the vesicles by this method. I looked up some works on genito-urinary surgery to see what advice they gave as to the removal of tuberculous seminal vesicles. The information they contained was not altogether encouraging. Watson Cheyne says: "Some surgeons have performed elaborate operations for the removal of tubercular seminal vesicles before suppuration has taken place. It is doubtful, however, whether an operation of this kind should ever be performed as it must be very extensive and the affection is usually secondary and therefore does not warrant it." Lydston says: "Any of the radical operations performed on the prostate and seminal vesicles for malignant or tubercular disease are, in the author's opinion, absolutely unjustifiable. The operator displays brilliancy of technic and boldness of surgical enterprise, but no other ends are conserved." Taylor says: "In the vast majority of cases, operative treatment is not to be thought of, unless suppuration has occurred in the sac, when its contents must be evacuated through a perineal incision, the cavity cleaned and packed with iodoform gauze. These patients should be sent to a suitable climate and receive the regular treatment for tuberculous subjects."

In spite of these remarks I still felt that an attempt should be made to remove the disease from my patient. I decided to follow the steps of Young's operation for perineal prostatectomy, hoping by the use of his tractor to bring the vesicles well within reach. I do not intend to describe the steps of the operation, as this was admirably done by Dr. C. A K. Ball at this Academy last session, a full account of which appears in last year's Transactions. The two dangers I feared were that in separating the adherent seminal vesicle from the bladder I might injure the ureter, the other that the veins surrounding the vesicles and prostate might cause dangerous hæmorrhage. As a precaution against the second I gave the patient drachm doses of chloride of calcium night and morning for three days before the operation. Whether this had any effect or not I cannot say, but the amount of blood lost during the operation was very slight. I removed the testicle and as much of the cord as I could from the front; then closing the inguinal wound I removed through the perineum the ends of both vasa deferentia, vesiculæ seminales, and the prostate. I had no great difficulty in separating the upper part of the right vesicle from the ureter, but the portion near the prostate was firmly attached to the bladder wall; either I used too much force with the tractor or had gone too deeply, for the blade of the instrument perforated the bladder wall where the vesicle had been attached to it. I made no attempt to close this opening but passed into the bladder two No. 12 catheters, one through the urethra and the second through the perineal wound and packed firmly round this perineal drain with iodoform gauze. The gauze plugs were removed on the second day, the perineal tube on the fourth day, and the urethral catheter on the seventh day. On the eighth day the patient was allowed up; he had then no difficulty in passing urine, had perfect control over the bladder, and there was no leakage from the perineal wound. On two occasions later some slight leakage occurred from this wound but did not last for more than a day and since then the wound has kept dry and has healed well.

Six months later I examined this patient. His bladder was quite healthy and the wound at the side of the trigone was firmly healed; the urine was normal. No return of the disease could be felt by the rectum. His general health was good; he had put on over a stone in weight since the operation. I hope that this case is cured.

CASE 6.—In August, 1905, another case of the same kind came under my care, with the exception that the patient was younger, only 19 years old, and that the one testicle was removed about a year before the disease appeared in the second. The cases were almost the same and I will not weary you with what would be almost a repetition of the one I have just described to you. The vesicles were not adherent to the same extent and came away without any injury to the bladder wall. The perineal wound was slower in closing. The boy was up on the eighth day and had perfect control of his bladder from this time onwards, yet for nearly a month there was a slight leakage of urine through the perineal wound every time he micturated. By the end of September he was able to resume his work and has since kept quite well and is putting on weight. It is much too soon to say there will be no recurrence of the disease in this case but his condition leads me to hope that he also is cured. The entire operation did not exceed in either case 45 minutes. This time included the removal of the testicle and cord by an inguinal incision and the prostate and vesicles by the perineal. There was no shock in either case but each patient received a saline transfusion before he left the operating table.

In conclusion let me recall to you a few important points. 1. That infection may readily pass along a normal vas to the vesicle or prostate; the fact that the vas above a diseased testis feels healthy is no proof that the tubercle has not extended to the vesicles. 2. That when both testicles and seminal vesicles are infected radical treatment alone is likely to be followed by success. 3. That where the disease is confined to the seminal tract it can be completely removed and that without any great risk to the patient. 4. That in all probability the patient is functionally no worse after such an operation than he is after a partial operation on both testes.

My thanks are due to Mr. T. E. Gordon who assisted me at the first operation and to Mr. F. T. Heuston who helped me at the second and also to Professor A. F. Dixon for much help and advice in the anatomy of the seminal region.

Dublin.

A CASE OF ACUTE YELLOW ATROPHY OF THE LIVER.

BY HENRY C. KEATES, M.B., B.S. LOND.,
CAPTAIN, INDIAN MEDICAL SERVICE.

THE patient whose illness is now described was a Pathan recruit of the 51st Sikhs frontier force and was admitted into the regimental hospital at Fort Lockhart on March 22nd, 1906, for "jaundice." He was a strong, healthy-looking man, aged 18 years, and had never been in hospital before. He did not come of his own accord to hospital but he was noticed to be jaundiced when a medical inspection of a company of Pathans was being held and accordingly was sent to hospital. He had come up to the fort on the preceding day from Hangoo, a small post 15 miles away, and stated that he had been of a yellow colour for two days. His condition on admission was as follows. He had marked jaundice, his conjunctivæ were yellow, and his skin was of a saffron yellow tint. His urine contained a considerable quantity of bile but no albumin. His fæces were quite white. His pulse-rate was not slow, being 80, quite regular, and of good volume. His temperature was normal. An examination of the chest revealed nothing abnormal. Liver dulness commenced at the upper border of the sixth rib in front on the right side and in the back the tenth and eleventh spaces were dull. In the axillary line dulness extended up to the eighth rib. The liver and spleen could not be felt by abdominal palpation. The tongue was clean and the appetite was fair. He did not complain of anything except that he felt a little weak and that he had a certain amount of pain and discomfort in the epigastric region. It was thought to be an ordinary case of catarrhal jaundice. He was ordered a purge of calomel, followed by magnesium sulphate in the morning and a mixture containing 10 grains each of bismuth subnitrate and sodium bicarbonate three time daily.

The following notes were made during the progress of the case. "March 24th.—Patient is in much the same condition; he does not complain of any special discomfort. Jaundice is somewhat increased. Two grains of calomel were ordered to be taken nightly. April 2nd.—Nothing of note happened till this date when his temperature rose to 103·6° F. in the evening. During the last few days he has been rather restless and disinclined to move. His pulse-rate for the week has averaged 68 and his temperature has been quite normal. His appetite has been fair. April 3rd.—His temperature this morning was 100° and his pulse-rate was 88. Ten grains of quinine were ordered thrice daily. April 4th.—His temperature after rising to 103° in the evening became normal this morning. He appears much weaker to-day. Neither the spleen nor liver is enlarged and both appear normal in size. He is now extremely jaundiced, the tears and saliva are tinged with bile, and the mucous membranes and tongue have a yellow tinge. The tongue is slightly furred. There is slight tenderness on pressure in the epigastric region. The bowels have been open once daily since admission, the motions being quite white. April 6th.—There has been no more fever but patient is in a lethargic condition. He will not trouble to answer questions, objects to taking medicine, and is very irritable. His pulse-rate is somewhat higher, averaging 80. He has been put on a milk and farinaceous diet. April 7th.—He is bleeding slightly from the gums to-day but the latter look normal and are not spongy. Lime-juice in doses of two ounces daily was ordered. April 8th.—Patient is in much the same condition. The skin itches considerably, especially over the chest and back. There are patches of erythema on his chest. Yesterday and to-day there has been slight diarrhœa, yesterday six motions and to-day three. The nightly dose of calomel is stopped. April 10th.—Patient is delirious to-day. He is dirty, passing urine and and fæces in his bed. He sometimes stands upon his bed and urinates on the floor. He is very noisy at times and strongly objects to taking any medicine. He was singing during the night. Tongue dirty and covered with thick fur. His face has become sunken and he has vomited twice. The vomit is tinged with bile. His skin over the chest and back is peeling in large flakes and is apparently itching greatly, as he is continually scratching himself. The pulse-rate is sometimes now as high as 90. The diarrhœa has ceased. A mixture containing five minims of liquor strychninæ and ten grains of ammonium chloride was ordered thrice daily. April 11th.—Patient was more quiet during the night as he had been given a sleeping draught consisting of 20 grains each of chloral and potassium bromide. He is talking coherently this morning but has again passed urine on the floor. April 12th.—Patient not so noisy to-day. He has not again soiled his bed but has passed urine on the floor. April 13th.—The urine was examined again to-day. It has a specific gravity of 1020 and an acid reaction. It contains much bile and traces of albumin. Microscopically it contains a few granular casts, a few blood corpuscles, and some crystals of leucin. The liver dulness to-day is much diminished in area. In front dulness commences on the right side of the chest along the costal margin, that is to say, at the level of the lower border of the eighth rib. The sixth and seventh spaces are resonant; the eighth and ninth spaces are dull. There is no dulness below the costal margin, nor can the liver be felt. In the right axilla there is dulness in the ninth, tenth, and eleventh spaces and behind on the right side in the eleventh space. The spleen is not enlarged. Hæmorrhage from the gums still continues but there is no vomiting now. Patient is more sensible to-day but he is restless and very weak. Pulse feeble and rapid, its rate being 120. There is distinct tenderness on pressure over the left lobe of the liver in the epigastric region. April 14th.—The patient is more delirious to-day. He is passing urine in his bed. Last night he had a small rise of temperature to 99·4°. In the front of the chest the liver dulness has practically disappeared. There is only impaired resonance along the border of the ninth rib in front. The pulse-rate is 112. April 15th.—Patient is in a semi comatose condition to-day. He is lying on his back with his eyes shut and occasionally murmurs. He cannot be roused. He is constantly expectorating in all directions. His pulse-rate is 134. He will not take any nourishment and has to be forcibly fed with milk To-day there is some slight dulness in the sixth right space in front. The chest below this is resonant. His urine contained a trace of albumin. On evaporating some urine a few tyrosin crystals were found and leucin crystals as before. His head was shaved and cold compresses were applied. April 16th.—Patient was completely comatose to-day. His breathing was very shallow and his pulse feeble and rapid with a rate between 130 and 140. In the morning he was thought by the sick attendants to be dead. Both respirations and pulse became feebler and he died from exhaustion at mid-day." A post-mortem examination was asked for but was refused by his relatives.

I have no doubt that this was a typical case of acute yellow atrophy of the liver but until the mental symptoms became marked and vomiting occurred I thought that it was a severe case of catarrhal jaundice. When the patient became delirious and vomiting and bleeding from the gums occurred it was evident that a simple jaundice could not account for all these symptoms. When it was found that the liver dulness which had previously been normal was greatly diminished and that leucin crystals appeared in the urine there seemed little doubt of the diagnosis. I had no means at hand to determine the amount of urea in the urine and so I cannot say whether it was diminished or not. No tyrosin crystals were seen in the urine until the day before his death; the leucin crystals were, however, fairly numerous. Osler states that the total number of recorded cases is 240. About 70 per cent. of these have been women, so it appears to be a disease of extreme rarity in men. I could obtain no information as to the causation. Previously to this illness the man was perfectly healthy, there were no signs of syphilis, and being a Mahomedan he had probably never touched alcohol. The liver must have been greatly diminished in size, as it was only with very light percussion that even impaired resonance could be obtained over the hepatic area at the end of his illness. There was no great tendency to hæmorrhage; the only one that occurred was from the gums. No enlargement of the spleen was found, although this is generally stated to be the case. The jaundice was most intense but it did not show any tendency to increase with the advent of head symptoms; on the contrary, it appeared to be somewhat diminished towards the end. A peculiarity of the jaundice was that both the tears and saliva were tinged with bile. I much regret that no post-mortem examination could be held, as every case of this rare disease is worth recording.

Fort Lockhart, Samana, India.

ON DEEP ALCOHOL INJECTIONS IN FACIAL AND OTHER NEURALGIAS AND IN HISTRIONIC SPASM.

BY DR. F. OSTWALT.

FOR some years past I have made a special study of the treatment of facial neuralgia. My aim has been to find a therapeutic method by which a serious surgical operation might be avoided, even in very rebellious and chronic cases of tic douloureux, the uncertainty of the final result being too great to warrant such dangerous operations as those recommended in such cases. In some not too severe cases of supraorbital neuralgia I succeeded in relieving the patients by giving them once or twice daily, during a couple of weeks, local baths, lasting half an hour each, of superheated dry air by means of a special apparatus called by me "Thermaërophore."[1] It was not until 1904 that I was put in possession of a method giving entirely satisfactory results in more than 90 per cent. of all cases. The principle of the method alluded to depends in the main on the injection of nerve-destroying substances upon the nerve trunk, a treatment suggested for the first time in 1887 by Pitres and Vaillard and practically applied, since three or four years only, by Schlösser. I believe that I have improved upon this method in some essential points. We are now enabled to reach by our injections not only the third but also the second and first branches of the fifth nerve at the very point where they emerge from the apertures at the base of the skull. Consequently, the number of cases to be cured by these deep injections has considerably increased. The addition of cocaine or stovaine to the alcohol seems also to be a slight improvement.

I now proceed in the following way. Let us suppose that we have to deal with what I believe is the most frequent condition in Fothergill's disease, neuralgia of the second and third divisions of the fifth nerve. I screw my bayonet-shaped needle on a syringe filled with about a fluid drachm of alcohol at 80 per cent., mixed with a sixth of a grain of cocaine or stovaine. After having previously disinfected the mouth and cocainised the mucous membrane at the point of the puncture I introduce my needle directly behind the alveolus of the wisdom tooth into the mucous membrane of the upper fornix of the vestibule of the affected side of the mouth and pass it through the, here rather thick, submucous tissue. I then push the needle through the external pterygoid muscle or around its lower border until it touches the external pterygoid plate. Then I move the needle in the zygomatic fossa slowly and carefully upwards along the external pterygoid plate until it comes in contact with the infra-temporal surface of the great wing of the sphenoid bone. Now I slide the point of the needle backwards in the corner between this infra-temporal surface and the before-mentioned external pterygoid plate as long as I feel the resistance of bone. As soon as this resistance ceases and the point of my needle encounters soft tissue I have arrived at the foramen ovale. I have to push the needle only a little (about a half to one line) further up in order to be sure that it touches the inferior maxillary nerve at the point of its emergence from the skull. I now inject very slowly, and with many interruptions, from one-third to two-thirds of a fluid drachm of my solution of cocaine or stovaine in alcohol, guiding the needle round about the foramen ovale and directing the jet of alcohol particularly towards those bundles which contain the nerve fibres supplying the affected parts of the head. The injection at the foramen ovale is soon followed by formication and torpor of the different branches of the inferior maxillary nerve and if there has existed a neuralgic paroxysm before and at the beginning of the injection it is, as a rule, cut short by this latter. As soon as the injection in the third division of the fifth nerve has been terminated I draw back the needle about a line, then I slide it forwards, always in contact with the bone, in the aforesaid corner between the infra-temporal surface of the great wing of the sphenoid bone and the external pterygoid plate, until I feel that the bone resistance ceases here again. This is the case at the anterior and median, rather sharp border of the infra-temporal surface of the great wing—i.e., at the boundary line between the zygomatic and the spheno-maxillary fossa.[2] The needle must now be pushed straight upwards about as much as two and a half or three lines in order to meet the foramen rotundum and the trunk of the superior maxillary nerve coming out of this hole. After some practice one feels if in pushing it up one directs the body of the syringe very slightly forwards in order to make the point of the needle slide backwards on the anterior surface of the upper part of the pterygoid process—I say, one then feels distinctly the small bridge of bone that above separates the foramen rotundum from the sphenoidal fissure.

---

[1] Annales d'Oculistique, vol. cxxxiii., p. 197.

After having thus ascertained that the point of my needle is exactly where I desire it to be I very slowly and with many pauses inject again about one-third of a fluid drachm of alcohol upon the second division of the fifth nerve at its point of emergence from the skull. In the rather infrequent case of simultaneous neuralgia of the first and second or the first, second, and third divisions of the fifth nerve I only need to push my needle, after the injection of the foramen rotundum, about a line more upwards. I then reach, after having passed over the afore-mentioned bridge of separating bone, the posterior lower end of the sphenoidal fissure, just at the place where the ophthalmic division of the fifth nerve passes from the middle cranial fossa to the orbit. A single puncture, followed by three successive injections, thus enables me to obtain a temporary incomplete paralysis of all the three divisions of the fifth nerve—i.e., an anæsthesia extending all over one side of the anterior half of the head from the vertex to the chin, including the nostril, the palate, and half the tongue. Even the masticatory muscles as a rule participate in this incomplete paralysis, to a certain degree at least.

I may say we are performing in this way a rather inoffensive, transient resection of the Gasserian ganglion. Transient it is, because the incomplete paralysis does not very often last more than a few hours or days. Sometimes it disappears only after some weeks, even after two or three months. It shows that the alcohol injections produce a degenerative process in the nerve, according to the experiments described years ago by Pitres and Vaillard. This degeneration is never more than temporary; the nerve always recovers its normal state and function, after a space of time varying from one case to another, as I have stated before—only the condition of pathological irritability which produced the neuralgia does not return at the same time, at least in the very great majority of cases. A single puncture will seldom be sufficient to cure the neuralgia. No doubt we rarely succeed the very first time in acting upon all altered nerve fibres together. Generally two, three, or four, sometimes even more sittings are needed in order to remove the pain entirely. But, as a rule, patients obtain great relief immediately after the first operation and this gives them courage and confidence to persevere in the treatment. I generally wait five or seven days between two interventions at the same place. This is the time, as a rule, that the œdematous swelling, which follows the injection, takes to disappear. In the case where, from the outset or after a previous injection at the foramina of the base of the skull, the neuralgia is localised in one of the peripheral branches of the fifth nerve I inject the alcohol solution on more peripheral, but nevertheless still sufficiently deep, points of the three divisions of this nerve, following therein exactly the precepts of Schlösser. The spot of the injection is then far backwards under the orbital vault for the terminal branches of the ophthalmic nerve, at the very end of the infra-orbital canal or groove for those of the superior maxillary nerve, and behind the ramus of the lower jaw for those of the inferior maxillary division of the fifth nerve. If these more peripheral injections do not completely triumph over the neuralgia I once more attack the suffering nerves at the apertures of the base of the skull.

Time can be gained by making the injections sometimes at the foramina of the base, sometimes more peripherally, because in that way one is not obliged to wait for the complete or nearly complete disappearance of the swelling which ensues. As a rule it is not advisable for operations upon the same branch of the fifth nerve to follow each other at too close intervals, because sometimes an injection, which is at first apparently quite inefficient, after a week's or a fortnight's delay leads to an entirely satisfactory result. It is evident that the technique of these punctures, especially of those at the foramina of the base of the skull, are not so very simple; they require a hand accustomed to rather delicate surgical work. The needle has to be directed with precision right on to the nerve, which is, of course, inaccessible to sight and touch; it has then to bring the nerve-destroying agent into contact with the nerve fibres. But we must not advance our needle any farther than absolutely necessary in order not to wound blood-vessels or vital organs in the neighbourhood. A perfect knowledge of the anatomy of the skull and of the varieties of its conformation is, of course, indispensable. It is evident that one succeeds only after some practice in obtaining a positive result in every case which is amenable to treatment by these injections—i.e., as has been mentioned already, in at least nine-tenths of the whole number. It is more than probable that in the remaining one-tenth the cause of the neuralgia lies within the cranial cavity. At any rate, it seems to me that facial neuralgia has much more often a peripheral origin than Pitres and Verger thought, guiding themselves by the efficiency or inefficiency of their cocaine injections *loco dolenti*.[3]

In order to show that one really is able, not only on the bare cranium but also on the intact head, to reach with the needle the three divisions of the fifth nerve at the points where they emerge from the apertures at the base of the skull, I injected melted red tallow on the dead subject in the Anatomical Institute of the Parisian Medical School, proceeding exactly in the same way as in the case of living patients. Then I dissected the head and convinced myself that the consolidated tallow included the nerve trunks at the desired points. I had the honour of demonstrating the preparation in question at a combined sitting of the Sections of Medicine and Neurology of the Fifteenth International Congress of Medicine at Lisbon. It illustrates in a very striking manner the superiority of my method. The so often affected second division of the fifth nerve particularly benefits by the improved process. Previously, the deeper branches of this division (the spheno-palatine nerves, the posterior dental nerves, the zygomatico-temporal nerve) could not be reached by the injections.
